CHAPTER

ONE

GETTING STARTED

If you need to build the library first, start with *Building The Library*. Some Linux distributions include packages for Botan, so building from source may not be required on your system.

1.1 Examples

Some examples of usage are included in this documentation. However a better source for example code is in the implementation of the command line interface (https://github.com/randombit/botan/tree/master/src/cli), which was intentionally written to act as practical examples of usage.

1.2 Books and other references

You should have some knowledge of cryptography *before* trying to use the library. This is an area where it is very easy to make mistakes, and where things are often subtle and/or counterintuitive. Obviously the library tries to provide things at a high level precisely to minimize the number of ways things can go wrong, but naive use will almost certainly not result in a secure system.

Especially recommended are:

- *Cryptography Engineering* by Niels Ferguson, Bruce Schneier, and Tadayoshi Kohno
- Security Engineering – A Guide to Building Dependable Distributed Systems (https://www.cl.cam.ac.uk/~rja14/book.html) by Ross Anderson
- Handbook of Applied Cryptography (http://www.cacr.math.uwaterloo.ca/hac/) by Alfred J. Menezes, Paul C. Van Oorschot, and Scott A. Vanstone

If you're doing something non-trivial or unique, you might want to at the very least ask for review/input at a place such as the metzdowd (http://www.metzdowd.com/mailman/listinfo/cryptography) or randombit (https://lists.randombit.net/mailman/listinfo/cryptography) mailing lists or the cryptography stack exchange (https://crypto.stackexchange.com/). And (if possible) pay a professional cryptographer or security company to review your design and code.

CHAPTER

TWO

PROJECT GOALS

Botan seeks to be a broadly applicable library that can be used to implement a range of secure distributed systems.

The library has the following project goals guiding changes. It does not succeed in all of these areas in every way just yet, but it describes the system that is the desired end result. Over time further progress is made in each.

- Secure and reliable. The implementations must of course be correct and well tested, and attacks such as side channels and fault attacks should be accounted for where necessary. The library should never crash, or invoke undefined behavior, regardless of circumstances.
- Implement schemes important in practice. It should be practical to implement any real-world crypto protocol using just what the library provides. It is worth some (limited) additional complexity in the library, in order to expand the set of applications which can easily adopt Botan.
- Ease of use. It should be straightforward for an application programmer to do whatever it is they need to do. There should be one obvious way to perform any operation. The API should be predicable, and follow the "principle of least astonishment" in its design. This is not just a nicety; confusing APIs often result in errors that end up compromising security.
- Simplicity of design, clarity of code, ease of review. The code should be easy to read and understand by other library developers, users seeking to better understand the behavior of the code, and by professional reviewers looking for bugs. This is important because bugs in convoluted code can easily escape multiple expert reviews, and end up living on for years.
- Well tested. The code should be correct against the spec, with as close to 100% test coverage as possible. All available static and dynamic analysis tools at our disposal should be used, including fuzzers, symbolic execution, and protocol specific tools. Within reason, all warnings from compilers and static analyzers should be addressed, even if they seem like false positives, because that maximizes the signal value of new warnings from the tool.
- Safe defaults. Policies should aim to be highly restrictive by default, and if they must be made less restrictive by certain applications, it should be obvious to the developer that they are doing something unsafe.
- Post quantum security. Possibly a practical quantum computer that can break RSA and ECC will never be built, but the future is notoriously hard to predict. It seems prudent to begin designing and deploying systems now which have at least the option of using a post-quantum scheme. Botan provides a conservative selection of algorithms thought to be post-quantum secure.
- Performance. Botan does not in every case strive to be faster than every other software implementation, but performance should be competitive and over time new optimizations are identified and applied.
- Support whatever I/O mechanism the application wants. Allow the application to control all aspects of how the network is contacted, and ensure the API makes asynchronous operations easy to handle. This both insulates Botan from system-specific details and allows the application to use whatever networking style they please.
- Portability to modern systems. Botan does not run everywhere, and we actually do not want it to (see non-goals below). But we do want it to run on anything that someone is deploying new applications on. That includes both

major platforms like Windows, Linux, Android and iOS, and also promising new systems such as IncludeOS and Fuchsia.

- Well documented. Ideally every public API would have some place in the manual describing its usage.
- Useful command line utility. The botan command line tool should be flexible and featured enough to replace similar tools such as `openssl` for everyday users.

2.1 Non-Goals

There are goals some crypto libraries have, but which Botan actively does not seek to address.

- Deep embedded support. Botan requires a heap, C++ exceptions, and RTTI, and at least in terms of performance optimizations effectively assumes a 32 or 64 bit processor. It is not suitable for deploying on, say FreeRTOS running on a MSP430, or smartcard with an 8 bit CPU and 256 bytes RAM. A larger SoC, such as a Cortex-A7 running Linux, is entirely within scope.
- Implementing every crypto scheme in existence. The focus is on algorithms which are in practical use in systems deployed now, as well as promising algorithms for future deployment. Many algorithms which were of interest in the past but never saw widespread deployment and have no compelling benefit over other designs have been removed to simplify the codebase.
- Portable to obsolete systems. There is no reason for crypto software to support ancient OS platforms like SunOS or Windows 2000, since these unpatched systems are completely unsafe anyway. The additional complexity supporting such platforms just creates more room for bugs.
- Portable to every C++ compiler ever made. Over time Botan moves forward to both take advantage of new language/compiler features, and to shed workarounds for dealing with bugs in ancient compilers, allowing further simplifications in the codebase. The set of supported compilers is fixed for each new release branch, for example Botan 2.x will always support GCC 4.8. But a future 3.x release version will likely increase the required versions for all compilers.
- FIPS 140 validation. The primary developer was (long ago) a consultant with a NIST approved testing lab. He does not have a positive view of the process or results, particularly when it comes to Level 1 software validations. The only benefit of a Level 1 validation is to allow for government sales, and the cost of validation includes enormous amounts of time and money, adding 'checks' that are useless or actively harmful, then freezing the software so security updates cannot be applied in the future. It does force a certain minimum standard (ie, FIPS Level 1 does assure AES and RSA are probably implemented correctly) but this is an issue of interop not security since Level 1 does not seriously consider attacks of any kind. Any security budget would be far better spent on a review from a specialized crypto consultancy, who would look for actual flaws.

  That said it would be easy to add a "FIPS 140" build mode to Botan, which just disabled all the builtin crypto and wrapped whatever the most recent OpenSSL FIPS module exports.
- Educational purposes. The library code is intended to be easy to read and review, and so might be useful in an educational context. However it does not contain any toy ciphers (unless you count DES and RC4) nor any tools for simple cryptanalysis. Generally the manual and source comments assume previous knowledge on the basic concepts involved.
- User proof. Some libraries provide a very high level API in an attempt to save the user from themselves. Occasionally they succeed. It would be appropriate and useful to build such an API on top of Botan, but Botan itself wants to cover a broad set of uses cases and some of these involve having pointy things within reach.

CHAPTER

THREE

SUPPORT INFORMATION

3.1 Supported Platforms

For Botan 2, the tier-1 supported platforms are

- Linux x86-64, GCC 4.8 or higher
- Linux x86-64, Clang 3.5 or higher
- Linux aarch64, GCC 4.8+
- Linux ppc64le, GCC 4.8+
- Windows x86-64, Visual C++ 2015 and 2017

These platforms are all tested by continuous integration, and the developers have access to hardware in order to test patches. Problems affecting these platforms are considered release blockers.

For Botan 2, the tier-2 supported platforms are

- Linux x86-32, GCC 4.8+
- Linux arm32, GCC 4.8+
- Windows x86-64, MinGW GCC
- Apple OS X x86-64, XCode Clang
- iOS arm32/arm64, XCode Clang
- Android arm32, NDK Clang
- FreeBSD x86-64, Clang 3.8+
- IncludeOS x86-32, Clang 3.8+
- Windows x86-64, Visual C++ 2013

Some (but not all) of the tier-2 platforms are tested by CI. Things should mostly work, and if problems are encountered, the Botan devs will probably be able to help. But they are not as well tested as tier-1.

Of course many other modern OSes such as OpenBSD, NetBSD, AIX, Solaris or QNX are also probably fine (Botan has been tested on all of them successfully in the past), but none of the core developers run these OSes and may not be able to help so much in debugging problems. Patches to improve the build for these platforms are welcome, as are any reports of successful use.

In theory any working C++11 compiler is fine but in practice, we only test with GCC, Clang, and Visual C++. There is support in the build system for several commercial C++ compilers (Intel, PGI, Sun Studio, Ekopath, etc) all of which worked with older (C++98) versions of both the code and the compilers, but it is not known if the latest versions of these compilers can compile the library properly.

3.2 Branch Support Status

Following table provides the support status for Botan branches as of August 2018. Any branch not listed here (including 1.11) is no longer supported. Dates in the future are approximate.

Branch	First Release	End of Active Development	End of Life
1.8	2008-12-08	2010-08-31	2016-02-13
1.10	2011-06-20	2012-07-10	2018-12-31
2.x	2017-01-06	2020?	2022 or later

"Active development" refers to adding new features and optimizations. At the conclusion of the active development phase, only bugfixes are applied.

3.3 Getting Help

To get help with Botan, open an issue on GitHub (https://github.com/randombit/botan/issues)

3.4 Custom Development or Support

Jack Lloyd, the primary developer, is available for projects including custom development, extended support, developer training, and reviewing code or protocol specifications for security flaws. Email him for more information.

CHAPTER

FOUR

BUILDING THE LIBRARY

This document describes how to build Botan on Unix/POSIX and Windows systems. The POSIX oriented descriptions should apply to most common Unix systems (including OS X), along with POSIX-ish systems like BeOS, QNX, and Plan 9. Currently, systems other than Windows and POSIX (such as VMS, MacOS 9, OS/390, OS/400, ...) are not supported by the build system, primarily due to lack of access. Please contact the maintainer if you would like to build Botan on such a system.

Botan's build is controlled by configure.py, which is a Python (https://www.python.org) script. Python 2.6 or later is required.

For the impatient, this works for most systems:

```
$ ./configure.py [--prefix=/some/directory]
$ make
$ make install
```

Or using `nmake`, if you're compiling on Windows with Visual C++. On platforms that do not understand the '#!' convention for beginning script files, or that have Python installed in an unusual spot, you might need to prefix the `configure.py` command with `python` or `/path/to/python`:

```
$ python ./configure.py [arguments]
```

4.1 Configuring the Build

The first step is to run `configure.py`, which is a Python script that creates various directories, config files, and a Makefile for building everything. This script should run under a vanilla install of Python 2.6, 2.7, or 3.x.

The script will attempt to guess what kind of system you are trying to compile for (and will print messages telling you what it guessed). You can override this process by passing the options `--cc`, `--os`, and `--cpu`.

You can pass basically anything reasonable with `--cpu`: the script knows about a large number of different architectures, their sub-models, and common aliases for them. You should only select the 64-bit version of a CPU (such as "sparc64" or "mips64") if your operating system knows how to handle 64-bit object code - a 32-bit kernel on a 64-bit CPU will generally not like 64-bit code.

By default the script tries to figure out what will work on your system, and use that. It will print a display at the end showing which algorithms have and have not been enabled. For instance on one system we might see lines like:

```
INFO: Skipping (dependency failure): certstor_sqlite3 sessions_sqlite3
INFO: Skipping (incompatible CPU): aes_power8
INFO: Skipping (incompatible OS): darwin_secrandom getentropy win32_stats
INFO: Skipping (incompatible compiler): aes_armv8 pmull sha1_armv8 sha2_32_armv8
```

(continues on next page)

(continued from previous page)

```
INFO: Skipping (no enabled compression schemes): compression
INFO: Skipping (requires external dependency): bearssl boost bzip2 lzma openssl␣
↪sqlite3 tpm zlib
```

The ones that are skipped because they are require an external dependency have to be explicitly asked for, because they rely on third party libraries which your system might not have or that you might not want the resulting binary to depend on. For instance to enable zlib support, add `--with-zlib` to your invocation of `configure.py`. All available modules can be listed with `--list-modules`.

You can control which algorithms and modules are built using the options `--enable-modules=MODS` and `--disable-modules=MODS`, for instance `--enable-modules=zlib` and `--disable-modules=xtea,idea`. Modules not listed on the command line will simply be loaded if needed or if configured to load by default. If you use `--minimized-build`, only the most core modules will be included; you can then explicitly enable things that you want to use with `--enable-modules`. This is useful for creating a minimal build targeting to a specific application, especially in conjunction with the amalgamation option; see *The Amalgamation Build*.

For instance:

```
$ ./configure.py --minimized-build --enable-modules=rsa,eme_oaep,emsa_pssr
```

will set up a build that only includes RSA, OAEP, PSS along with any required dependencies. Note that a minimized build does not by default include any random number generator, which is needed for example to generate keys, nonces and IVs. See *Random Number Generators* on which random number generators are available.

The option `--module-policy=POL` enables modules required by and disables modules prohibited by a text policy in `src/build-data/policy`. Additional modules can be enabled if not prohibited by the policy. Currently available policies include `bsi`, `nist` and `modern`:

```
$ ./configure.py --module-policy=bsi --enable-modules=tls,xts
```

4.1.1 Cross Compiling

Cross compiling refers to building software on one type of host (say Linux x86-64) but creating a binary for some other type (say MinGW x86-32). This is completely supported by the build system. To extend the example, we must tell *configure.py* to use the MinGW tools:

```
$ ./configure.py --os=mingw --cpu=x86_32 --cc-bin=i686-w64-mingw32-g++ --ar=i686-w64-
↪mingw32-ar
...
$ make
...
$ file botan.exe
botan.exe: PE32 executable (console) Intel 80386, for MS Windows
```

You can also specify the alternate tools by setting the *CXX* and *AR* environment variables (instead of the *–cc-bin* and *–ar-command* options), as is commonly done with autoconf builds.

4.1.2 On Unix

The basic build procedure on Unix and Unix-like systems is:

```
$ ./configure.py [--enable-modules=<list>] [--cc=CC]
$ make
$ ./botan-test
```

If that fails with an error about not being able to find libbotan.so, you may need to set `LD_LIBRARY_PATH`:

```
$ LD_LIBRARY_PATH=. ./botan-test
```

If the tests look OK, install:

```
$ make install
```

On Unix systems the script will default to using GCC; use `--cc` if you want something else. For instance use `--cc=icc` for Intel C++ and `--cc=clang` for Clang.

The `make install` target has a default directory in which it will install Botan (typically `/usr/local`). You can override this by using the `--prefix` argument to `configure.py`, like so:

```
$ ./configure.py --prefix=/opt <other arguments>
```

On some systems shared libraries might not be immediately visible to the runtime linker. For example, on Linux you may have to edit `/etc/ld.so.conf` and run `ldconfig` (as root) in order for new shared libraries to be picked up by the linker. An alternative is to set your `LD_LIBRARY_PATH` shell variable to include the directory that the Botan libraries were installed into.

4.1.3 On macOS

A build on macOS works much like that on any other Unix-like system.

To build a universal binary for macOS, you need to set some additional build flags. Do this with the *configure.py* flag *–cc-abi-flags*:

```
--cc-abi-flags="-force_cpusubtype_ALL -mmacosx-version-min=10.4 -arch i386 -arch ppc"
```

4.1.4 On Windows

Note: The earliest versions of Windows supported are Windows 7 and Windows 2008 R2

You need to have a copy of Python installed, and have both Python and your chosen compiler in your path. Open a command shell (or the SDK shell), and run:

```
$ python configure.py --cc=msvc --os=windows
$ nmake
$ botan-test.exe
$ nmake install
```

Botan supports the nmake replacement Jom (https://wiki.qt.io/Jom) which enables you to run multiple build jobs in parallel.

For MinGW, use:

```
$ python configure.py --cc=gcc --os=mingw
$ make
```

By default the install target will be `C:\botan`; you can modify this with the `--prefix` option.

When building your applications, all you have to do is tell the compiler to look for both include files and library files in `C:\botan`, and it will find both. Or you can move them to a place where they will be in the default compiler search paths (consult your documentation and/or local expert for details).

4.1.5 For iOS using XCode

For iOS, you typically build for 3 architectures: armv7 (32 bit, older iOS devices), armv8-a (64 bit, recent iOS devices) and x86_64 for the iPhone simulator. You can build for these 3 architectures and then create a universal binary containing code for all of these architectures, so you can link to Botan for the simulator as well as for an iOS device.

To cross compile for armv7, configure and make with:

```
$ ./configure.py --os=ios --prefix="iphone-32" --cpu=armv7 --cc=clang \
                 --cc-abi-flags="-arch armv7"
xcrun --sdk iphoneos make install
```

To cross compile for armv8-a, configure and make with:

```
$ ./configure.py --os=ios --prefix="iphone-64" --cpu=armv8-a --cc=clang \
                 --cc-abi-flags="-arch arm64"
xcrun --sdk iphoneos make install
```

To compile for the iPhone Simulator, configure and make with:

```
$ ./configure.py --os=ios --prefix="iphone-simulator" --cpu=x86_64 --cc=clang \
                 --cc-abi-flags="-arch x86_64"
xcrun --sdk iphonesimulator make install
```

Now create the universal binary and confirm the library is compiled for all three architectures:

```
$ xcrun --sdk iphoneos lipo -create -output libbotan-2.a \
               iphone-32/lib/libbotan-2.a \
               iphone-64/lib/libbotan-2.a \
               iphone-simulator/lib/libbotan-2.a
$ xcrun --sdk iphoneos lipo -info libbotan-2.a
Architectures in the fat file: libbotan-2.a are: armv7 x86_64 armv64
```

The resulting static library can be linked to your app in Xcode.

4.1.6 For Android

Instructions for building the library on Android can be found here (https://www.danielseither.de/blog/2013/03/building-the-botan-library-for-android/).

4.2 Other Build-Related Tasks

4.2.1 Building The Documentation

There are two documentation options available, Sphinx and Doxygen. Sphinx will be used if `sphinx-build` is detected in the PATH, or if `--with-sphinx` is used at configure time. Doxygen is only enabled if `--with-doxygen` is used. Both are generated by the makefile target `docs`.

4.2.2 The Amalgamation Build

You can also configure Botan to be built using only a single source file; this is quite convenient if you plan to embed the library into another application.

To generate the amalgamation, run `configure.py` with whatever options you would ordinarily use, along with the option `--amalgamation`. This will create two (rather large) files, `botan_all.h` and `botan_all.cpp`, plus (unless the option `--single-amalgamation-file` is used) also some number of files like `botan_all_aesni.cpp` and `botan_all_sse2.cpp` which need to be compiled with the appropriate compiler flags to enable that instruction set. The ISA specific files are only generated if there is code that requires them, so you can simplify your build. The `--minimized-build` option (described elsewhere in this documentation) is also quite useful with the amalgamation.

Whenever you would have included a botan header, you can then include `botan_all.h`, and include `botan_all.cpp` along with the rest of the source files in your build. If you want to be able to easily switch between amalgamated and non-amalgamated versions (for instance to take advantage of prepackaged versions of botan on operating systems that support it), you can instead ignore `botan_all.h` and use the headers from `build/include` as normal.

You can also build the library using Botan's build system (as normal) but utilizing the amalgamation instead of the individual source files by running something like `./configure.py --amalgamation && make`. This is essentially a very simple form of link time optimization; because the entire library source is visible to the compiler, it has more opportunities for interprocedural optimizations. Additionally, amalgamation builds usually have significantly shorter compile times for full rebuilds.

4.2.3 Modules Relying on Third Party Libraries

Currently `configure.py` cannot detect if external libraries are available, so using them is controlled explicitly at build time by the user using

- `--with-bzip2` enables the filters providing bzip2 compression and decompression. Requires the bzip2 development libraries to be installed.
- `--with-zlib` enables the filters providing zlib compression and decompression. Requires the zlib development libraries to be installed.
- `--with-lzma` enables the filters providing lzma compression and decompression. Requires the lzma development libraries to be installed.
- `--with-sqlite3` enables using sqlite3 databases in various contexts (TLS session cache, PSK database, etc).
- `--with-openssl` adds an engine that uses OpenSSL for some ciphers, hashes, and public key operations. OpenSSL 1.0.2 or later is supported. LibreSSL can also be used.
- `--with-tpm` adds support for using TPM hardware via the TrouSerS library.
- `--with-boost` enables using some Boost libraries. In particular Boost.Filesystem is used for a few operations (but on most platforms, a native API equivalent is available), and Boost.Asio is used to provide a few extra TLS related command line utilities.

4.2.4 Multiple Builds

It may be useful to run multiple builds with different configurations. Specify `--with-build-dir=<dir>` to set up a build environment in a different directory.

4.2.5 Setting Distribution Info

The build allows you to set some information about what distribution this build of the library comes from. It is particularly relevant to people packaging the library for wider distribution, to signify what distribution this build is from. Applications can test this value by checking the string value of the macro `BOTAN_DISTRIBUTION_INFO`. It can be set using the `--distribution-info` flag to `configure.py`, and otherwise defaults to "unspecified". For instance,

a Gentoo (https://www.gentoo.org) ebuild might set it with `--distribution-info="Gentoo ${PVR}"` where `${PVR}` is an ebuild variable automatically set to a combination of the library and ebuild versions.

4.2.6 Local Configuration Settings

You may want to do something peculiar with the configuration; to support this there is a flag to `configure.py` called `--with-local-config=<file>`. The contents of the file are inserted into `build/build.h` which is (indirectly) included into every Botan header and source file.

4.2.7 Enabling or Disabling Use of Certain OS Features

Botan uses compile-time flags to enable or disable use of certain operating specific functions. You can also override these at build time if desired.

The default feature flags are given in the files in `src/build-data/os` in the `target_features` block. For example Linux defines flags like `proc_fs`, `getauxval`, and `sockets`. The `configure.py` option `--list-os-features` will display all the feature flags for all operating system targets.

To disable a default-enabled flag, use `--without-os-feature=feat1,feat2,...`

To enable a flag that isn't otherwise enabled, use `--with-os-feature=feat`. For example, modern Linux systems support the `getentropy` call, but it is not enabled by default because many older systems lack it. However if you know you will only deploy to recently updated systems you can use `--with-os-feature=getentropy` to enable it.

A special case if dynamic loading, which applications for certain environments will want to disable. There is no specific feature flag for this, but `--disable-modules=dyn_load` will prevent it from being used.

Note: Disabling `dyn_load` module will also disable the PKCS #11 wrapper, which relies on dynamic loading.

4.2.8 Configuration Parameters

There are some configuration parameters which you may want to tweak before building the library. These can be found in `build.h`. This file is overwritten every time the configure script is run (and does not exist until after you run the script for the first time).

Also included in `build/build.h` are macros which let applications check which features are included in the current version of the library. All of them begin with `BOTAN_HAS_`. For example, if `BOTAN_HAS_BLOWFISH` is defined, then an application can include `<botan/blowfish.h>` and use the Blowfish class.

`BOTAN_MP_WORD_BITS`: This macro controls the size of the words used for calculations with the MPI implementation in Botan. It must be set to either 32 or 64 bits. The default is chosen based on the target processor. There is normally no reason to change this.

`BOTAN_DEFAULT_BUFFER_SIZE`: This constant is used as the size of buffers throughout Botan. The default should be fine for most purposes, reduce if you are very concerned about runtime memory usage.

4.3 Building Applications

4.3.1 Unix

Botan usually links in several different system libraries (such as `librt` or `libz`), depending on which modules are configured at compile time. In many environments, particularly ones using static libraries, an application has to link against the same libraries as Botan for the linking step to succeed. But how does it figure out what libraries it *is* linked against?

The answer is to ask the `botan` command line tool using the `config` and `version` commands.

`botan version`: Print the Botan version number.

`botan config prefix`: If no argument, print the prefix where Botan is installed (such as `/opt` or `/usr/local`).

`botan config cflags`: Print options that should be passed to the compiler whenever a C++ file is compiled. Typically this is used for setting include paths.

`botan config libs`: Print options for which libraries to link to (this will include a reference to the botan library itself).

Your `Makefile` can run `botan config` and get the options necessary for getting your application to compile and link, regardless of whatever crazy libraries Botan might be linked against.

4.3.2 Windows

No special help exists for building applications on Windows. However, given that typically Windows software is distributed as binaries, this is less of a problem - only the developer needs to worry about it. As long as they can remember where they installed Botan, they just have to set the appropriate flags in their Makefile/project file.

4.4 Language Wrappers

4.4.1 Building the Python wrappers

The Python wrappers for Botan use ctypes and the C89 API so no special build step is required, just import botan2.py

See *Python Bindings* for more information about the Python bindings.

CHAPTER

FIVE

VERSIONING

All versions are of the tuple (major,minor,patch).

As of Botan 2.0.0, Botan uses semantic versioning. The minor number increases if any feature addition is made. The patch version is used to indicate a release where only bug fixes were applied. If an incompatible API change is required, the major version will be increased.

The library has functions for checking compile-time and runtime versions.

The build-time version information is defined in *botan/build.h*

BOTAN_VERSION_MAJOR
: The major version of the release.

BOTAN_VERSION_MINOR
: The minor version of the release.

BOTAN_VERSION_PATCH
: The patch version of the release.

BOTAN_VERSION_DATESTAMP
: Expands to an integer of the form YYYYMMDD if this is an official release, or 0 otherwise. For instance, 1.10.1, which was released on July 11, 2011, has a *BOTAN_VERSION_DATESTAMP* of 20110711.

BOTAN_DISTRIBUTION_INFO
: New in version 1.9.3.

  A macro expanding to a string that is set at build time using the `--distribution-info` option. It allows a packager of the library to specify any distribution-specific patches. If no value is given at build time, the value is the string "unspecified".

BOTAN_VERSION_VC_REVISION
: New in version 1.10.1.

  A macro expanding to a string that is set to a revision identifier corresponding to the source, or "unknown" if this could not be determined. It is set for all official releases, and for builds that originated from within a git checkout.

The runtime version information, and some helpers for compile time version checks, are included in *botan/version.h*

std::string **version_string**()
: Returns a single-line string containing relevant information about this build and version of the library in an unspecified format.

uint32_t **version_major**()
: Returns the major part of the version.

uint32_t **version_minor**()
: Returns the minor part of the version.

uint32_t **version_patch**()
Returns the patch part of the version.

uint32_t **version_datestamp**()
Return the datestamp of the release (or 0 if the current version is not an official release).

std::string **runtime_version_check**(uint32_t *major*, uint32_t *minor*, uint32_t *patch*)
Call this function with the compile-time version being built against, eg:

```
Botan::runtime_version_check(BOTAN_VERSION_MAJOR, BOTAN_VERSION_MINOR, BOTAN_
↪VERSION_PATCH)
```

It will return an empty string if the versions match, or otherwise an error message indicating the discrepancy. This only is useful in dynamic libraries, where it is possible to compile and run against different versions.

BOTAN_VERSION_CODE_FOR(maj, min, patch)
Return a value that can be used to compare versions. The current (compile-time) version is available as the macro *BOTAN_VERSION_CODE*. For instance, to choose one code path for version 2.1.0 and later, and another code path for older releases:

```
#if BOTAN_VERSION_CODE >= BOTAN_VERSION_CODE_FOR(2,1,0)
   // 2.1+ code path
#else
   // code path for older versions
#endif
```

CHAPTER

SIX

MEMORY CONTAINER

A major concern with mixing modern multi-user OSes and cryptographic code is that at any time the code (including secret keys) could be swapped to disk, where it can later be read by an attacker, or left floating around in memory for later retrieval.

For this reason the library uses a `std::vector` with a custom allocator that will zero memory before deallocation, named via typedef as `secure_vector`. Because it is simply a STL vector with a custom allocator, it has an identical API to the `std::vector` you know and love.

Some operating systems offer the ability to lock memory into RAM, preventing swapping from occurring. Typically this operation is restricted to privileged users (root or admin), however some OSes including Linux and FreeBSD allow normal users to lock a small amount of memory. On these systems, allocations first attempt to allocate out of this small locked pool, and then if that fails will fall back to normal heap allocations.

The `secure_vector` template is only meant for primitive data types (bytes or ints): if you want a container of higher level Botan objects, you can just use a `std::vector`, since these objects know how to clear themselves when they are destroyed. You cannot, however, have a `std::vector` (or any other container) of `Pipe` objects or filters, because these types have pointers to other filters, and implementing copy constructors for these types would be both hard and quite expensive (vectors of pointers to such objects is fine, though).

CHAPTER

SEVEN

RANDOM NUMBER GENERATORS

class RandomNumberGenerator

The base class for all RNG objects, is declared in `rng.h`.

void **randomize**(uint8_t **output_array*, size_t *length*)

Places *length* random bytes into the provided buffer.

void **randomize_with_input**(uint8_t **data*, size_t *length*, **const** uint8_t **extra_input*, size_t *extra_input_len*)

Like randomize, but first incorporates the additional input field into the state of the RNG. The additional input could be anything which parameterizes this request. Not all RNG types accept additional inputs, the value will be silently ignored when not supported.

void **randomize_with_ts_input**(uint8_t **data*, size_t *length*)

Creates a buffer with some timestamp values and calls `randomize_with_input`

uint8_t **next_byte**()

Generates a single random byte and returns it. Note that calling this function several times is much slower than calling `randomize` once to produce multiple bytes at a time.

void **add_entropy**(**const** uint8_t **data*, size_t *length*)

Incorporates provided data into the state of the PRNG, if at all possible. This works for most RNG types, including the system and TPM RNGs. But if the RNG doesn't support this operation, the data is dropped, no error is indicated.

bool **accepts_input**() **const**

This function returns `false` if it is known that this RNG object cannot accept external inputs. In this case, any calls to *`RandomNumberGenerator::add_entropy`* will be ignored.

void **reseed_from_rng**(*RandomNumberGenerator* &*rng*, size_t *poll_bits* = BOTAN_RNG_RESEED_POLL_BITS)

Reseed by calling `rng` to acquire `poll_bits` data.

7.1 RNG Types

Several different RNG types are implemented. Some access hardware RNGs, which are only available on certain platforms. Others are mostly useful in specific situations.

Generally prefer using either the system RNG, or else `AutoSeeded_RNG` which is intended to provide best possible behavior in a userspace PRNG.

7.1.1 System_RNG

On systems which support it, in `system_rng.h` you can access a shared reference to a process global instance of the system PRNG (using interfaces such as `/dev/urandom`, `getrandom`, `arc4random`, or `RtlGenRandom`):

RandomNumberGenerator &**system_rng**()
Returns a reference to the system RNG

There is also a wrapper class `System_RNG` which simply invokes on the return value of `system_rng()`. This is useful in situations where you may sometimes want to use the system RNG and a userspace RNG in others, for example:

```
std::unique_ptr<Botan::RandomNumberGenerator> rng;
#if defined(BOTAN_HAS_SYSTEM_RNG)
rng.reset(new System_RNG);
#else
rng.reset(new AutoSeeded_RNG);
#endif
```

Unlike nearly any other object in Botan it is acceptable to share a single instance of `System_RNG` between threads, because the underlying RNG is itself thread safe due to being serialized by a mutex in the kernel itself.

7.1.2 AutoSeeded_RNG

AutoSeeded_RNG is type naming a 'best available' userspace PRNG. The exact definition of this has changed over time and may change in the future, fortunately there is no compatibility concerns when changing any RNG since the only expectation is it produces bits indistinguishable from random.

Note: Like most other classes in Botan, it is not safe to share an instance of `AutoSeeded_RNG` among multiple threads without serialization.

The current version uses HMAC_DRBG with either SHA-384 or SHA-256. The initial seed is generated either by the system PRNG (if available) or a default set of entropy sources. These are also used for periodic reseeding of the RNG state.

7.1.3 HMAC_DRBG

HMAC DRBG is a random number generator designed by NIST and specified in SP 800-90A. It seems to be the most conservative generator of the NIST approved options.

It can be instantiated with any HMAC but is typically used with SHA-256, SHA-384, or SHA-512, as these are the hash functions approved for this use by NIST.

HMAC_DRBG's constructors are:

class HMAC_DRBG

HMAC_DRBG(std::unique_ptr<*MessageAuthenticationCode*> *prf*, *RandomNumberGenerator* &*underlying_rng*, size_t *reseed_interval* = BOTAN_RNG_DEFAULT_RESEED_INTERVAL, size_t *max_number_of_bytes_per_request* = 64 * 1024)
Creates a DRBG which will automatically reseed as required by making calls to `underlying_rng` either after being invoked `reseed_interval` times, or if use of `fork` system call is detected.

You can disable automatic reseeding by setting `reseed_interval` to zero, in which case `underlying_rng` will only be invoked in the case of `fork`.

The specification of HMAC DRBG requires that each invocation produce no more than 64 kibibytes of data. However, the RNG interface allows producing arbitrary amounts of data in a single request. To accommodate this, `HMAC_DRBG` treats requests for more data as if they were multiple requests each of (at most) the maximum size. You can specify a smaller maximum size with `max_number_of_bytes_per_request`. There is normally no reason to do this.

HMAC_DRBG(std::unique_ptr<*MessageAuthenticationCode*> *prf*, Entropy_Sources &*entropy_sources*, size_t *reseed_interval* = BOTAN_RNG_DEFAULT_RESEED_INTERVAL, size_t *max_number_of_bytes_per_request* = 64 * 1024)
Like above function, but instead of an RNG taking a set of entropy sources to seed from as required.

HMAC_DRBG(std::unique_ptr<*MessageAuthenticationCode*> *prf*, *RandomNumberGenerator* &*underlying_rng*, Entropy_Sources &*entropy_sources*, size_t *reseed_interval* = BOTAN_RNG_DEFAULT_RESEED_INTERVAL, size_t *max_number_of_bytes_per_request* = 64 * 1024)
Like above function, but taking both an RNG and a set of entropy sources to seed from as required.

HMAC_DRBG(std::unique_ptr<*MessageAuthenticationCode*> *prf*)
Creates an unseeded DRBG. You must explicitly provide seed data later on in order to use this RNG. This is primarily useful for deterministic key generation.

Since no source of data is available to automatically reseed, automatic reseeding is disabled when this constructor is used. If the RNG object detects that `fork` system call was used without it being subsequently reseeded, it will throw an exception.

HMAC_DRBG(**const** std::string &*hmac_hash*)
Like the constructor just taking a PRF, except instead of a PRF object, a string specifying what hash to use with HMAC is provided.

7.1.4 ChaCha_RNG

This is a very fast userspace PRNG based on ChaCha20 and HMAC(SHA-256). The key for ChaCha is derived by hashing entropy inputs with HMAC. Then the ChaCha keystream generator is run, first to generate the new HMAC key (used for any future entropy additions), then the desired RNG outputs.

This RNG composes two primitives thought to be secure (ChaCha and HMAC) in a simple and well studied way (the extract-then-expand paradigm), but is still an ad-hoc and non-standard construction. It is included because it is roughly 20x faster then HMAC_DRBG (basically running as fast as ChaCha can generate keystream bits), and certain applications need access to a very fast RNG.

One thing applications using `ChaCha_RNG` need to be aware of is that for performance reasons, no backtracking resistance is implemented in the RNG design. An attacker who recovers the `ChaCha_RNG` state can recover the output backwards in time to the last rekey and forwards to the next rekey.

An explicit reseeding (*`RandomNumberGenerator::add_entropy`*) or providing any input to the RNG (*`RandomNumberGenerator::randomize_with_ts_input`*, *`RandomNumberGenerator::randomize_with_input`*) is sufficient to cause a reseeding. Or, if a RNG or entropy source was provided to the `ChaCha_RNG` constructor, then reseeding will be performed automatically after a certain interval of requests.

7.1.5 RDRAND_RNG

This RNG type directly calls the x86 `rdrand` instruction. If the instruction is not available it will throw at runtime, you can check beforehand by calling `Botan::CPUID::has_rdrand()`.

7.1.6 TPM_RNG

This RNG type allows using the RNG exported from a TPM chip.

7.1.7 PKCS11_RNG

This RNG type allows using the RNG exported from a hardware token accessed via PKCS11.

7.2 Entropy Sources

An `EntropySource` is an abstract representation of some method of gather "real" entropy. This tends to be very system dependent. The *only* way you should use an `EntropySource` is to pass it to a PRNG that will extract entropy from it – never use the output directly for any kind of key or nonce generation!

`EntropySource` has a pair of functions for getting entropy from some external source, called `fast_poll` and `slow_poll`. These pass a buffer of bytes to be written; the functions then return how many bytes of entropy were gathered.

Note for writers of `EntropySource` subclasses: it isn't necessary to use any kind of cryptographic hash on your output. The data produced by an EntropySource is only used by an application after it has been hashed by the `RandomNumberGenerator` that asked for the entropy, thus any hashing you do will be wasteful of both CPU cycles and entropy.

The following entropy sources are currently used:

- The system RNG (`arc4random`, `/dev/urandom`, or `RtlGenRandom`).
- RDRAND and RDSEED are used if available, but not counted as contributing entropy
- `/dev/random` and `/dev/urandom`. This may be redundant with the system RNG
- `getentropy`, only used on OpenBSD currently
- `/proc` walk: read files in `/proc`. Last ditch protection against flawed system RNG.
- Win32 stats: takes snapshot of current system processes. Last ditch protection against flawed system RNG.

7.3 Fork Safety

On Unix platforms, the `fork()` and `clone()` system calls can be used to spawn a new child process. Fork safety ensures that the child process doesn't see the same output of random bytes as the parent process. Botan tries to ensure fork safety by feeding the process ID into the internal state of the random generator and by automatically reseeding the random generator if the process ID changed between two requests of random bytes. However, this does not protect against PID wrap around. The process ID is usually implemented as a 16 bit integer. In this scenario, a process will spawn a new child process, which exits the parent process and spawns a new child process himself. If the PID wrapped around, the second child process may get assigned the process ID of it's grandparent and the fork safety can not be ensured.

Therefore, it is strongly recommended to explicitly reseed any userspace random generators after forking a new process. If this is not possible in your application, prefer using the system PRNG instead.

CHAPTER

EIGHT

HASH FUNCTIONS AND CHECKSUMS

Hash functions are one-way functions, which map data of arbitrary size to a fixed output length. Most of the hash functions in Botan are designed to be cryptographically secure, which means that it is computationally infeasible to create a collision (finding two inputs with the same hash) or preimages (given a hash output, generating an arbitrary input with the same hash). But note that not all such hash functions meet their goals, in particular MD4 and MD5 are trivially broken. However they are still included due to their wide adoption in various protocols.

The class `HashFunction` is defined in *botan/hash.h*.

Using a hash function is typically split into three stages: initialization, update, and finalization (often referred to as a IUF interface). The initialization stage is implicit: after creating a hash function object, it is ready to process data. Then update is called one or more times. Calling update several times is equivalent to calling it once with all of the arguments concatenated. After completing a hash computation (eg using `final`), the internal state is reset to begin hashing a new message.

class HashFunction

size_t **output_length**()
: Return the size (in *bytes*) of the output of this function.

void **update**(**const** uint8_t **input*, size_t *length*)
: Updates the computation with *input*.

void **update**(uint8_t *input*)
: Updates the computation with *input*.

void **update**(**const** std::vector<uint8_t> &*input*)
: Updates the computation with *input*.

void **update**(**const** std::string &*input*)
: Updates the computation with *input*.

void **final**(uint8_t **out*)
: Finalize the calculation and place the result into `out`. For the argument taking an array, exactly `output_length` bytes will be written. After you call `final`, the algorithm is reset to its initial state, so it may be reused immediately.

secure_vector<uint8_t> **final**()
: Similar to the other function of the same name, except it returns the result in a newly allocated vector.

secure_vector<uint8_t> **process**(**const** uint8_t *in*[], size_t *length*)
: Equivalent to calling `update` followed by `final`.

secure_vector<uint8_t> **process**(**const** std::string &*in*)
: Equivalent to calling `update` followed by `final`.

8.1 Code Example

Assume we want to calculate the SHA-256, SHA-384, and SHA-3 hash digests of the STDIN stream using the Botan library.

```
#include <botan/hash.h>
#include <botan/hex.h>
#include <iostream>
int main ()
   {
   std::unique_ptr<Botan::HashFunction> hash1(Botan::HashFunction::create("SHA-256"));
   std::unique_ptr<Botan::HashFunction> hash2(Botan::HashFunction::create("SHA-384"));
   std::unique_ptr<Botan::HashFunction> hash3(Botan::HashFunction::create("SHA-3"));
   std::vector<uint8_t> buf(2048);

   while(std::cin.good())
      {
      //read STDIN to buffer
      std::cin.read(reinterpret_cast<char*>(buf.data()), buf.size());
      size_t readcount = std::cin.gcount();
      //update hash computations with read data
      hash1->update(buf.data(),readcount);
      hash2->update(buf.data(),readcount);
      hash3->update(buf.data(),readcount);
      }
   std::cout << "SHA-256: " << Botan::hex_encode(hash1->final()) << std::endl;
   std::cout << "SHA-384: " << Botan::hex_encode(hash2->final()) << std::endl;
   std::cout << "SHA-3: " << Botan::hex_encode(hash3->final()) << std::endl;
   return 0;
   }
```

8.2 Available Hash Functions

The following cryptographic hash functions are implemented. If in doubt, any of SHA-384, SHA-3, BLAKE2b, or Skein-512 are fine choices.

8.2.1 BLAKE2b

Available if `BOTAN_HAS_BLAKE2B` is defined.

A recently designed hash function. Very fast on 64-bit processors. Can output a hash of any length between 1 and 64 bytes, this is specified by passing a value to the constructor with the desired length.

8.2.2 GOST-34.11

Available if `BOTAN_HAS_GOST_34_11` is defined.

Russian national standard hash. It is old, slow, and has some weaknesses. Avoid it unless you must.

8.2.3 Keccak-1600

Available if `BOTAN_HAS_KECCAK` is defined.

An older (and incompatible) variant of SHA-3, but sometimes used. Prefer SHA-3 in new code.

8.2.4 MD4

Available if `BOTAN_HAS_MD4` is defined.

An old hash function that is now known to be trivially breakable. It is very fast, and may still be suitable as a (non-cryptographic) checksum.

8.2.5 MD5

Available if `BOTAN_HAS_MD5` is defined.

Widely used, now known to be broken.

8.2.6 RIPEMD-160

Available if `BOTAN_HAS_RIPEMD160` is defined.

A 160 bit hash function, quite old but still thought to be secure (up to the limit of 2**80 computation required for a collision which is possible with any 160 bit hash function). Somewhat deprecated these days.

8.2.7 SHA-1

Available if `BOTAN_HAS_SHA1` is defined.

Widely adopted NSA designed hash function. Starting to show significant signs of weakness, and collisions can now be generated. Avoid in new designs.

8.2.8 SHA-256

Available if `BOTAN_HAS_SHA2_32` is defined.

Relatively fast 256 bit hash function, thought to be secure.

Also includes the variant SHA-224. There is no real reason to use SHA-224.

8.2.9 SHA-512

Available if `BOTAN_HAS_SHA2_64` is defined.

SHA-512 is faster than SHA-256 on 64-bit processors. Also includes the truncated variants SHA-384 and SHA-512/256.

8.2.10 SHA-3

Available if `BOTAN_HAS_SHA3` is defined.

The new NIST standard hash. Fairly slow.

8.2.11 SHAKE (SHAKE-128, SHAKE-256)

Available if `BOTAN_HAS_SHAKE` is defined.

These are actually XOFs (extensible output functions) based on SHA-3, which can output a value of any length.

8.2.12 SM3

Available if `BOTAN_HAS_SM3` is defined.

Chinese national hash function, 256 bit output. Widely used in industry there. Fast and seemingly secure.

8.2.13 Skein-512

Available if `BOTAN_HAS_SKEIN_512` is defined.

A contender for the NIST SHA-3 competition. Very fast on 64-bit systems. Can output a hash of any length between 1 and 64 bytes. It also accepts a "personalization string" which can create variants of the hash. This is useful for domain separation.

8.2.14 Streebog (Streebog-256, Streebog-512)

Available if `BOTAN_HAS_STREEBOG` is defined.

Newly designed Russian national hash function. Due to use of input-dependent table lookups, it is vulnerable to side channels. There is no reason to use it unless compatibility is needed.

8.2.15 Tiger

Available if `BOTAN_HAS_TIGER` is defined.

An older 192-bit hash function, optimized for 64-bit systems. Possibly vulnerable to side channels due to its use of table lookups. Prefer Skein-512 or BLAKE2b in new code.

8.2.16 Whirlpool

Available if `BOTAN_HAS_WHIRLPOOL` is defined.

A 512-bit hash function standardized by ISO and NESSIE. Relatively slow, and due to the table based implementation it is (unlike almost all other hashes) potentially vulnerable to cache based side channels. Prefer Skein-512 or BLAKE2b in new code.

8.3 Hash Function Combiners

These are functions which combine multiple hash functions to create a new hash function. They are typically only used in specialized applications.

8.3.1 Parallel

Available if BOTAN_HAS_PARALLEL_HASH is defined.

Parallel simply concatenates multiple hash functions. For example "Parallel(SHA-256,SHA-512)" outputs a 256+512 bit hash created by hashing the input with both SHA-256 and SHA-512 and concatenating the outputs.

Note that due to the "multicollision attack" it turns out that generating a collision for multiple parallel hash functions is no harder than generating a collision for the strongest hash function.

8.3.2 Comp4P

Available if BOTAN_HAS_COMB4P is defined.

This combines two cryptographic hashes in such a way that preimage and collision attacks are provably at least as hard as a preimage or collision attack on the strongest hash.

8.4 Checksums

Note: Checksums are not suitable for cryptographic use, but can be used for error checking purposes.

8.4.1 Adler32

Available if BOTAN_HAS_ADLER32 is defined.

The Adler32 checksum is used in the zlib format. 32 bit output.

8.4.2 CRC24

Available if BOTAN_HAS_CRC24 is defined.

This is the CRC function used in OpenPGP. 24 bit output.

8.4.3 CRC32

Available if BOTAN_HAS_CRC32 is defined.

This is the 32-bit CRC used in protocols such as Ethernet, gzip, PNG, etc.

CHAPTER

NINE

BLOCK CIPHERS

Block ciphers are a n-bit permutation for some small n, typically 64 or 128 bits. They are a cryptographic primitive used to generate higher level operations such as authenticated encryption.

Warning: In almost all cases, a bare block cipher is not what you should be using. You probably want an authenticated cipher mode instead (see *Cipher Modes*) This interface is used to build higher level operations (such as cipher modes or MACs), or in the very rare situation where ECB is required, eg for compatibility with an existing system.

class BlockCipher

static std::unique_ptr<*BlockCipher*> **create**(**const** std::string &*algo_spec*, **const** std::string &*provider* = "")
Create a new block cipher object, or else return null.

static std::unique_ptr<*BlockCipher*> **create_or_throw**(**const** std::string &*algo_spec*, **const** std::string &*provider* = "")
Like `create`, except instead of returning null an exception is thrown if the cipher is not known.

void **set_key**(**const** uint8_t **key*, size_t *length*)
This sets the key to the value specified. Most algorithms only accept keys of certain lengths. If you attempt to call `set_key` with a key length that is not supported, the exception `Invalid_Key_Length` will be thrown.

In all cases, `set_key` must be called on an object before any data processing (encryption, decryption, etc) is done by that object. If this is not done, an exception will be thrown. thrown.

bool **valid_keylength**(size_t *length*) **const**
This function returns true if and only if *length* is a valid keylength for this algorithm.

size_t **minimum_keylength**() **const**
Return the smallest key length (in bytes) that is acceptable for the algorithm.

size_t **maximum_keylength**() **const**
Return the largest key length (in bytes) that is acceptable for the algorithm.

std::string **name**() **const**
Return a human readable name for this algorithm. This is guaranteed to round-trip with `create` and `create_or_throw` calls, ie create("Foo")->name() == "Foo"

void **clear**()
Zero out the key. The key must be reset before the cipher object can be used.

BlockCipher ***clone**() **const**
Return a newly allocated BlockCipher object of the same type as this one.

size_t **block_size**() **const**
: Return the size (in *bytes*) of the cipher.

size_t **parallelism**() **const**
: Return the parallelism underlying this implementation of the cipher. This value can vary across versions and machines. A return value of N means that encrypting or decrypting with N blocks can operate in parallel.

size_t **parallel_bytes**() **const**
: Returns `parallelism` multiplied by the block size as well as a small fudge factor. That's because even ciphers that have no implicit parallelism typically see a small speedup for being called with several blocks due to caching effects.

std::string **provider**() **const**
: Return the provider type. Default value is "base" but can be any arbitrary string. Other example values are "sse2", "avx2", "openssl".

void **encrypt_n**(**const** uint8_t *in*[], uint8_t *out*[], size_t *blocks*) **const**
: Encrypt *blocks* blocks of data, taking the input from the array *in* and placing the ciphertext into *out*. The two pointers may be identical, but should not overlap ranges.

void **decrypt_n**(**const** uint8_t *in*[], uint8_t *out*[], size_t *blocks*) **const**
: Decrypt *blocks* blocks of data, taking the input from the array *in* and placing the plaintext into *out*. The two pointers may be identical, but should not overlap ranges.

void **encrypt**(**const** uint8_t *in*[], uint8_t *out*[]) **const**
: Encrypt a single block. Equivalent to *encrypt_n*(in, out, 1).

void **encrypt**(uint8_t *block*[]) **const**
: Encrypt a single block. Equivalent to *encrypt_n*(block, block, 1)

void **decrypt**(**const** uint8_t *in*[], uint8_t *out*[]) **const**
: Decrypt a single block. Equivalent to *decrypt_n*(in, out, 1)

void **decrypt**(uint8_t *block*[]) **const**
: Decrypt a single block. Equivalent to *decrypt_n*(block, block, 1)

template<typename **Alloc**>
void **encrypt**(std::vector<uint8_t, *Alloc*> &*block*) **const**
: Assumes `block` is of a multiple of the block size.

template<typename **Alloc**>
void **decrypt**(std::vector<uint8_t, *Alloc*> &*block*) **const**
: Assumes `block` is of a multiple of the block size.

9.1 Code Example

For sheer demonstrative purposes, the following code encrypts a provided single block of plaintext with AES-256 using two different keys.

```
#include <botan/block_cipher.h>
#include <botan/hex.h>
#include <iostream>
int main ()
   {
   std::vector<uint8_t> key = Botan::hex_decode(
↪"000102030405060708090A0B0C0D0E0F101112131415161718191A1B1C1D1E1F");
   std::vector<uint8_t> block = Botan::hex_decode("00112233445566778899AABBCCDDEEFF");
```

(continues on next page)

(continued from previous page)

```
   std::unique_ptr<Botan::BlockCipher> cipher(Botan::BlockCipher::create("AES-256"));
   cipher->set_key(key);
   cipher->encrypt(block);
   std::cout << std::endl <<cipher->name() << "single block encrypt: " << Botan::hex_
↪encode(block);

   //clear cipher for 2nd encryption with other key
   cipher->clear();
   key = Botan::hex_decode(
↪"13371337133713371337133713371337133713371337133713371337133713371337");
   cipher->set_key(key);
   cipher->encrypt(block);

   std::cout << std::endl << cipher->name() << "single block encrypt: " << Botan::hex_
↪encode(block);
   return 0;
   }
```

9.2 Available Ciphers

Botan includes a number of block ciphers that are specific to particular countries, as well as a few that are included mostly due to their use in specific protocols such as PGP but not widely used elsewhere. The ciphers that seem best for new code are AES, Serpent, and Threefish-512. If you are developing new code and have no particular opinion, pick AES-256.

> **Warning:** Avoid any 64-bit block cipher in new designs. There are combinatoric issues that affect any 64-bit cipher that render it insecure when large amounts of data are processed.

9.2.1 AES

Comes in three variants, AES-128, AES-192, and AES-256.

The standard 128-bit block cipher. Many modern platforms offer hardware acceleration. However, on platforms without hardware support, AES implementations typically are vulnerable to side channel attacks. For x86 systems with SSSE3 but without AES-NI, Botan has an implementation which avoids known side channels.

Available if `BOTAN_HAS_AES` is defined.

9.2.2 ARIA

South Korean cipher used in industry there. No reason to use it otherwise.

Available if `BOTAN_HAS_ARIA` is defined.

9.2.3 Blowfish

A 64-bit cipher popular in the pre-AES era. Very slow key setup. Also used (with bcrypt) for password hashing.

Available if `BOTAN_HAS_BLOWFISH` is defined.

9.2.4 CAST-128

A 64-bit cipher, commonly used in OpenPGP.

Available if `BOTAN_HAS_CAST128` is defined.

9.2.5 CAST-256

A 128-bit cipher that was a contestant in the NIST AES competition. Rarely used, and now deprecated in Botan. Use AES or Serpent instead.

Available if `BOTAN_HAS_CAST256` is defined.

9.2.6 Camellia

Comes in three variants, Camellia-128, Camellia-192, and Camellia-256.

A Japanese design standardized by ISO, NESSIE and CRYPTREC. Somewhat common. Prefer AES or Serpent in new designs.

Available if `BOTAN_HAS_CAMELLIA` is defined.

9.2.7 Cascade

Creates a block cipher cascade, where each block is encrypted by two ciphers with independent keys. Useful if you're very paranoid. In practice any single good cipher (such as Serpent, SHACAL2, or AES-256) is more than sufficient.

Available if `BOTAN_HAS_CASCADE` is defined.

9.2.8 DES, 3DES, DESX

Originally designed by IBM and NSA in the 1970s. Today, DES's 56-bit key renders it insecure to any well-resourced attacker. DESX and 3DES extend the key length, and are still thought to be secure, modulo the limitation of a 64-bit block. All are somewhat common in some industries such as finance. Avoid in new code.

Available if `BOTAN_HAS_DES` is defined.

9.2.9 GOST-28147-89

A old 64-bit Russian cipher. Possible security issues. Avoid unless compatibility is needed.

Available if `BOTAN_HAS_GOST_28147_89` is defined.

9.2.10 IDEA

An older but still unbroken 64-bit cipher with a 128-bit key. Somewhat common due to its use in PGP. Avoid in new designs.

Available if `BOTAN_HAS_IDEA` is defined.

9.2.11 Kasumi

A 64-bit cipher used in 3GPP mobile phone protocols. There is no reason to use it outside of this context.

Available if `BOTAN_HAS_KASUMI` is defined.

9.2.12 Lion

A "block cipher construction" which can encrypt blocks of nearly arbitrary length. Built from a stream cipher and a hash function. Useful in certain protocols where being able to encrypt large or arbitrary length blocks is necessary.

Available if `BOTAN_HAS_LION` is defined.

9.2.13 MISTY1

A 64-bit Japanese cipher standardized by NESSIE and ISO. Seemingly secure, but quite slow and saw little adoption. No reason to use it in new code. The implementation in Botan is deprecated, and it is likely to be removed in a future release.

Available if `BOTAN_HAS_MISTY1` is defined.

9.2.14 Noekeon

A fast 128-bit cipher by the designers of AES. Easily secured against side channels.

Available if `BOTAN_HAS_NOEKEON` is defined.

9.2.15 SEED

A older South Korean cipher, widely used in industry there.

Available if `BOTAN_HAS_SEED` is defined.

9.2.16 SHACAL2

The 256-bit block cipher used inside SHA-256. Accepts up to a 512-bit key. Fast and seemingly very secure, but obscure. Standardized by NESSIE.

Available if `BOTAN_HAS_SHACAL2` is defined.

9.2.17 SM4

A 128-bit Chinese national cipher, required for use in certain commercial applications in China. Quite slow. Probably no reason to use it outside of legal requirements.

Available if `BOTAN_HAS_SM4` is defined.

9.2.18 Serpent

An AES contender. Widely considered the most conservative design. Fairly slow, especially if no SIMD instruction set is available.

Available if `BOTAN_HAS_SERPENT` is defined.

9.2.19 Threefish-512

A 512-bit tweakable block cipher that was used in the Skein hash function. Very fast on 64-bit processors.

Available if `BOTAN_HAS_THREEFISH_512` is defined.

9.2.20 Twofish

An AES contender. Somewhat complicated key setup and a "kitchen sink" design.

Available if `BOTAN_HAS_TWOFISH` is defined.

9.2.21 XTEA

A 64-bit cipher popular for its simple implementation. Avoid in new code.

Available if `BOTAN_HAS_XTEA` is defined.

CHAPTER

TEN

STREAM CIPHERS

In contrast to block ciphers, stream ciphers operate on a plaintext stream instead of blocks. Thus encrypting data results in changing the internal state of the cipher and encryption of plaintext with arbitrary length is possible in one go (in byte amounts). All implemented stream ciphers derive from the base class `StreamCipher` (*botan/stream_cipher.h*).

Warning: Using a stream cipher without an authentication code is extremely insecure, because an attacker can trivially modify messages. Prefer using an authenticated cipher mode such as GCM or SIV.

Warning: Encrypting more than one message with the same key requires careful management of initialization vectors. Otherwise the keystream will be reused, which causes the security of the cipher to completely fail.

class StreamCipher

std::string **name**() **const**
Returns a human-readable string of the name of this algorithm.

void **clear**()
Clear the key.

StreamCipher ***clone**() **const**
Return a newly allocated object of the same type as this one.

void **set_key**(**const** uint8_t **key*, size_t *length*)
Set the stream cipher key. If the length is not accepted, an `Invalid_Key_Length` exception is thrown.

bool **valid_keylength**(size_t *length*) **const**
This function returns true if and only if *length* is a valid keylength for the algorithm.

size_t **minimum_keylength**() **const**
Return the smallest key length (in bytes) that is acceptable for the algorithm.

size_t **maximum_keylength**() **const**
Return the largest key length (in bytes) that is acceptable for the algorithm.

bool **valid_iv_length**(size_t *iv_len*) **const**
This function returns true if and only if *length* is a valid IV length for the stream cipher. Some ciphers do not support IVs at all, and will return false for any value except zero.

size_t **default_iv_length**() **const**
Returns some default IV size, normally the largest IV supported by the cipher. If this function returns zero, then IVs are not supported and any call to `set_iv` with a non-empty value will fail.

void **set_iv**(**const** uint8_t *, size_t *len*)
: Load IV into the stream cipher state. This should happen after the key is set and before any operation (encrypt/decrypt/seek) is called.

  If the cipher does not support IVs, then a call with `len` equal to zero will be accepted and any other length will cause a `Invalid_IV_Length` exception.

void **seek**(uint64_t *offset*)
: Sets the state of the stream cipher and keystream according to the passed *offset*, exactly as if *offset* bytes had first been encrypted. The key and (if required) the IV have to be set before this can be called. Not all ciphers support seeking; such objects will throw `Not_Implemented` in this case.

void **cipher**(**const** uint8_t *in, uint8_t *out, size_t *n*)
: Processes *n* bytes plain/ciphertext from *in* and writes the result to *out*.

void **cipher1**(uint8_t *inout, size_t *n*)
: Processes *n* bytes plain/ciphertext in place. Acts like *cipher*(inout, inout, n).

void **encipher**(std::vector<uint8_t> *inout*)

void **encrypt**(std::vector<uint8_t> *inout*)

void **decrypt**(std::vector<uint8_t> *inout*)
: Processes plain/ciphertext *inout* in place. Acts like *cipher*(inout.data(), inout.data(), inout.size()).

10.1 Code Example

The following code encrypts a provided plaintext using ChaCha20.

```
#include <botan/stream_cipher.h>
#include <botan/auto_rng.h>
#include <botan/hex.h>
#include <iostream>

int main()
   {
   std::string plaintext("This is a tasty burger!");
   std::vector<uint8_t> pt(plaintext.data(),plaintext.data()+plaintext.length());
   const std::vector<uint8_t> key = Botan::hex_decode(
↪"000102030405060708090A0B0C0D0E0F101112131415161718191A1B1C1D1E1F");
   std::unique_ptr<Botan::StreamCipher> cipher(Botan::StreamCipher::create("ChaCha(20)
↪"));

   //generate fresh nonce (IV)
   std::unique_ptr<Botan::RandomNumberGenerator> rng(new Botan::AutoSeeded_RNG);
   std::vector<uint8_t> iv(8);
   rng->randomize(iv.data(),iv.size());

   //set key and IV
   cipher->set_key(key);
   cipher->set_iv(iv.data(),iv.size());
   cipher->encipher(pt);

   std::cout << cipher->name() << " with iv " << Botan::hex_encode(iv) << ": "
             << Botan::hex_encode(pt) << "\n";
   return 0;
   }
```

10.2 Available Stream Ciphers

Botan provides the following stream ciphers. If in doubt use ChaCha20 or CTR(AES-256).

10.2.1 CTR-BE

A cipher mode that converts a block cipher into a stream cipher. It offers parallel execution and can seek within the output stream, both useful properties.

CTR mode requires an IV which can be any length up to the block size of the underlying cipher. If it is shorter than the block size, sufficient zero bytes are appended.

It is possible to choose the width of the counter portion, which can improve performance somewhat, but limits the maximum number of bytes that can safely be encrypted. Different protocols have different conventions for the width of the counter portion. This is done by specifying with width (which must be at least 4 bytes, allowing to encrypt 2^{32} blocks of data) for example "CTR(AES-256,8)" to select a 64-bit counter.

(The `-BE` suffix refers to big-endian convention for the counter. This is the most common case.)

10.2.2 OFB

Another stream cipher based on a block cipher. Unlike CTR mode, it does not allow parallel execution or seeking within the output stream. Prefer CTR.

Available if `BOTAN_HAS_OFB` is defined.

10.2.3 ChaCha

A very fast cipher, now widely deployed in TLS as part of the ChaCha20Poly1305 AEAD. Can be used with 8 (fast but dangerous), 12 (balance), or 20 rounds (conservative). Even with 20 rounds, ChaCha is very fast. Use 20 rounds.

ChaCha supports an optional IV (which defaults to all zeros). It can be of length 64, 96 or (since 2.8) 192 bits. Using ChaCha with a 192 bit nonce is also known as XChaCha.

Available if `BOTAN_HAS_CHACHA` is defined.

10.2.4 Salsa20

An earlier iteration of the ChaCha design, this cipher is popular due to its use in the libsodium library. Prefer ChaCha.

Salsa supports an optional IV (which defaults to all zeros). It can be of length 64 or 192 bits. Using Salsa with a 192 bit nonce is also known as XSalsa.

Available if `BOTAN_HAS_SALSA20` is defined.

10.2.5 SHAKE-128

This is the SHAKE-128 XOF exposed as a stream cipher. It is slower than ChaCha and somewhat obscure. It does not support IVs or seeking within the cipher stream.

Available if `BOTAN_HAS_SHAKE_CIPHER` is defined.

10.2.6 RC4

An old and very widely deployed stream cipher notable for its simplicity. It does not support IVs or seeking within the cipher stream.

> **Warning:** RC4 is now badly broken. **Avoid in new code** and use only if required for compatibility with existing systems.

Available if `BOTAN_HAS_RC4` is defined.

CHAPTER

ELEVEN

MESSAGE AUTHENTICATION CODES (MAC)

A Message Authentication Code algorithm computes a tag over a message utilizing a shared secret key. Thus a valid tag confirms the authenticity and integrity of the message. Only entities in possession of the shared secret key are able to verify the tag.

Note: When combining a MAC with unauthenticated encryption mode, prefer to first encrypt the message and then MAC the ciphertext. The alternative is to MAC the plaintext, which depending on exact usage can suffer serious security issues. For a detailed discussion of this issue see the paper "The Order of Encryption and Authentication for Protecting Communications" by Hugo Krawczyk

---

The Botan MAC computation is split into five stages.

1. Instantiate the MAC algorithm.
2. Set the secret key.
3. Process IV.
4. Process data.
5. Finalize the MAC computation.

class MessageAuthenticationCode

std::string **name**() **const**
Returns a human-readable string of the name of this algorithm.

void **clear**()
Clear the key.

MessageAuthenticationCode ***clone**() **const**
Return a newly allocated object of the same type as this one.

void **set_key**(**const** uint8_t **key*, size_t *length*)
Set the shared MAC key for the calculation. This function has to be called before the data is processed.

bool **valid_keylength**(size_t *length*) **const**
This function returns true if and only if *length* is a valid keylength for the algorithm.

size_t **minimum_keylength**() **const**
Return the smallest key length (in bytes) that is acceptable for the algorithm.

size_t **maximum_keylength**() **const**
Return the largest key length (in bytes) that is acceptable for the algorithm.

void **start**(**const** uint8_t **nonce*, size_t *nonce_len*)
Set the IV for the MAC calculation. Note that not all MAC algorithms require an IV. If an IV is required,

the function has to be called before the data is processed. For algorithms that don't require it, the call can be omitted, or else called with `nonce_len` of zero.

void **update**(**const** uint8_t **input*, size_t *length*)
Process the passed data.

void **update**(**const** secure_vector<uint8_t> &*in*)
Process the passed data.

void **update**(uint8_t *in*)
Process a single byte.

void **final**(uint8_t **out*)
Complete the MAC computation and write the calculated tag to the passed byte array.

secure_vector<uint8_t> **final**()
Complete the MAC computation and return the calculated tag.

bool **verify_mac**(**const** uint8_t **mac*, size_t *length*)
Finalize the current MAC computation and compare the result to the passed `mac`. Returns `true`, if the verification is successful and false otherwise.

11.1 Code Examples

The following example computes an HMAC with a random key then verifies the tag.

#include <botan/mac.h> #include <botan/hex.h> #include <botan/system_rng.h> #include <assert.h>

std::string compute_mac(const std::string& msg, const Botan::secure_vector<uint8_t>& key) {
auto hmac = Botan::MessageAuthenticationCode::create_or_throw("HMAC(SHA-256)");

hmac->set_key(key); hmac->update(msg);

return Botan::hex_encode(hmac->final()); }

int main() { Botan::System_RNG rng;

const auto key = rng.random_vec(32); // 256 bit random key

// "Message" != "Mussage" so tags will also not match std::string tag1 = compute_mac("Message", key); std::string tag2 = compute_mac("Mussage", key); assert(tag1 != tag2);

// Recomputing with original input message results in identical tag std::string tag3 = compute_mac("Message", key); assert(tag1 == tag3); }

The following example code computes a AES-256 GMAC and subsequently verifies the tag. Unlike most other MACs, GMAC requires a nonce *which must not repeat or all security is lost*.

```
#include <botan/mac.h>
#include <botan/hex.h>
#include <iostream>

int main()
   {
   const std::vector<uint8_t> key = Botan::hex_decode(
↪"13371337133713371337133713371337133713371337133713371337133713371337");
   const std::vector<uint8_t> nonce = Botan::hex_decode("FFFFFFFFFFFFFFFFFFFFFFFF");
   const std::vector<uint8_t> data = Botan::hex_decode(
↪"6BC1BEE22E409F96E93D7E117393172A");
   std::unique_ptr<Botan::MessageAuthenticationCode>␣
↪mac(Botan::MessageAuthenticationCode::create("GMAC(AES-256)"));
```

(continues on next page)

(continued from previous page)

```
   if(!mac)
      return 1;
   mac->set_key(key);
   mac->start(nonce);
   mac->update(data);
   Botan::secure_vector<uint8_t> tag = mac->final();
   std::cout << mac->name() << ": " << Botan::hex_encode(tag) << std::endl;

   //Verify created MAC
   mac->start(nonce);
   mac->update(data);
   std::cout << "Verification: " << (mac->verify_mac(tag) ? "success" : "failure");
   return 0;
   }
```

The following example code computes a valid AES-128 CMAC tag and modifies the data to demonstrate a MAC verification failure.

```
#include <botan/mac.h>
#include <botan/hex.h>
#include <iostream>

  int main()
     {
     const std::vector<uint8_t> key = Botan::hex_decode(
↪"2B7E151628AED2A6ABF7158809CF4F3C");
     std::vector<uint8_t> data = Botan::hex_decode("6BC1BEE22E409F96E93D7E117393172A
↪");
     std::unique_ptr<Botan::MessageAuthenticationCode>␣
↪mac(Botan::MessageAuthenticationCode::create("CMAC(AES-128)"));
     if(!mac)
        return 1;
     mac->set_key(key);
     mac->update(data);
     Botan::secure_vector<uint8_t> tag = mac->final();
     //Corrupting data
     data.back()++;
     //Verify with corrupted data
     mac->update(data);
     std::cout << "Verification with malformed data: " << (mac->verify_mac(tag) ?
↪"success" : "failure");
     return 0;
     }
```

11.2 Available MACs

Currently the following MAC algorithms are available in Botan. In new code, default to HMAC with a strong hash like SHA-256 or SHA-384.

11.2.1 CBC-MAC

An older authentication code based on a block cipher. Serious security problems, in particular **insecure** if messages of several different lengths are authenticated. Avoid unless required for compatibility.

Available if BOTAN_HAS_CBC_MAC is defined.

11.2.2 CMAC

A modern CBC-MAC variant that avoids the security problems of plain CBC-MAC. Approved by NIST. Also sometimes called OMAC.

Available if BOTAN_HAS_CMAC is defined.

11.2.3 GMAC

GMAC is related to the GCM authenticated cipher mode. It is quite slow unless hardware support for carryless multiplications is available. A new nonce must be used with **each** message authenticated, or otherwise all security is lost.

Available if BOTAN_HAS_GMAC is defined.

11.2.4 HMAC

A message authentication code based on a hash function. Very commonly used.

Available if BOTAN_HAS_HMAC is defined.

11.2.5 Poly1305

A polynomial mac (similar to GMAC). Very fast, but tricky to use safely. Forms part of the ChaCha20Poly1305 AEAD mode. A new key must be used for **each** message, or all security is lost.

Available if BOTAN_HAS_POLY1305 is defined.

11.2.6 SipHash

A modern and very fast PRF. Produces only a 64-bit output. Defaults to "SipHash(2,4)" which is the recommended configuration, using 2 rounds for each input block and 4 rounds for finalization.

Available if BOTAN_HAS_SIPHASH is defined.

11.2.7 X9.19-MAC

A CBC-MAC variant sometimes used in finance. Always uses DES. Avoid unless required.

Available if BOTAN_HAS_X919_MAC is defined.

CHAPTER

TWELVE

CIPHER MODES

A block cipher by itself, is only able to securely encrypt a single data block. To be able to securely encrypt data of arbitrary length, a mode of operation applies the block cipher's single block operation repeatedly to encrypt an entire message.

All cipher mode implementations are are derived from the base class *Cipher_Mode*, which is declared in `botan/cipher_mode.h`.

Warning: Using an unauthenticted cipher mode without combining it with a *Message Authentication Codes (MAC)* is insecure. Prefer using an *AEAD Mode*.

class Cipher_Mode

void **set_key**(**const** uint8_t **key*, size_t *length*)
Set the symmetric key to be used.

bool **valid_keylength**(size_t *length*) **const**
This function returns true if and only if *length* is a valid keylength for the algorithm.

size_t **minimum_keylength**() **const**
Return the smallest key length (in bytes) that is acceptable for the algorithm.

size_t **maximum_keylength**() **const**
Return the largest key length (in bytes) that is acceptable for the algorithm.

void **start_msg**(**const** uint8_t **nonce*, size_t *nonce_len*)
Set the IV (unique per-message nonce) of the mode of operation and prepare for message processing.

void **start**(**const** std::vector<uint8_t> *nonce*)
Acts like *start_msg*(nonce.data(), nonce.size()).

void **start**(**const** uint8_t **nonce*, size_t *nonce_len*)
Acts like *start_msg*(nonce, nonce_len).

virtual size_t **update_granularity**() **const**
The *Cipher_Mode* interface requires message processing in multiples of the block size. Returns size of required blocks to update and 1, if the mode can process messages of any length.

virtual size_t **process**(uint8_t **msg*, size_t *msg_len*)
Process msg in place and returns bytes written. msg must be a multiple of *update_granularity*.

void **update**(secure_vector<uint8_t> *&buffer*, size_t *offset* = 0)
Continue processing a message in the buffer in place. The passed buffer's size must be a multiple of *update_granularity*. The first *offset* bytes of the buffer will be ignored.

size_t **minimum_final_size**() **const**
Returns the minimum size needed for *finish*.

void **finish**(secure_vector<uint8_t> &*final_block*, size_t *offset* = 0)
Finalize the message processing with a final block of at least *minimum_final_size* size. The first *offset* bytes of the passed final block will be ignored.

12.1 Code Example

The following code encrypts the specified plaintext using AES-128/CBC with PKCS#7 padding.

Warning: This example ignores the requirement to authenticate the ciphertext

Note: Simply replacing the string "AES-128/CBC/PKCS7" string in the example below with "AES-128/GCM" suffices to use authenticated encryption.

```
#include <botan/rng.h>
#include <botan/auto_rng.h>
#include <botan/cipher_mode.h>
#include <botan/hex.h>
#include <iostream>

int main()
   {
   Botan::AutoSeeded_RNG rng;

   const std::string plaintext("Your great-grandfather gave this watch to your␣
↪granddad for good luck. Unfortunately, Dane's luck wasn't as good as his old man's.
↪");
   const std::vector<uint8_t> key = Botan::hex_decode(
↪"2B7E151628AED2A6ABF7158809CF4F3C");

   std::unique_ptr<Botan::Cipher_Mode> enc = Botan::Cipher_Mode::create("AES-128/CBC/
↪PKCS7", Botan::ENCRYPTION);
   enc->set_key(key);

   //generate fresh nonce (IV)
   Botan::secure_vector<uint8_t> iv = rng.random_vec(enc->default_nonce_length());

   // Copy input data to a buffer that will be encrypted
   Botan::secure_vector<uint8_t> pt(plaintext.data(), plaintext.data()+plaintext.
↪length());

   enc->start(iv);
   enc->finish(pt);

   std::cout << enc->name() << " with iv " << Botan::hex_encode(iv) << " " <<␣
↪Botan::hex_encode(pt) << "\n";
   return 0;
   }
```

12.2 Available Unauthenticated Cipher Modes

Note: CTR and OFB modes are also implemented, but these are treated as `Stream_Ciphers` instead.

12.2.1 CBC

Available if `BOTAN_HAS_MODE_CBC` is defined.

CBC requires the plaintext be padded using a reversible rule. The following padding schemes are implemented

PKCS#7 (RFC5652) The last byte in the padded block defines the padding length p, the remaining padding bytes are set to p as well.

ANSI X9.23 The last byte in the padded block defines the padding length, the remaining padding is filled with 0x00.

OneAndZeros (ISO/IEC 7816-4) The first padding byte is set to 0x80, the remaining padding bytes are set to 0x00.

12.2.2 CFB

Available if `BOTAN_HAS_MODE_CFB` is defined.

CFB uses a block cipher to create a self-synchronizing stream cipher. It is used for example in the OpenPGP protocol. There is no reason to prefer it.

12.2.3 XTS

Available if `BOTAN_HAS_MODE_XTS` is defined.

XTS is a mode specialized for encrypting disk storage. XTS requires all inputs be at least 1 byte longer than the native block size of the cipher.

12.3 AEAD Mode

AEAD (Authenticated Encryption with Associated Data) modes provide message encryption, message authentication, and the ability to authenticate additional data that is not included in the ciphertext (such as a sequence number or header). It is a subclass of *Cipher_Mode*.

The AEAD interface can be used directly, or as part of the filter system by using `AEAD_Filter` (a subclass of `Keyed_Filter` which will be returned by *get_cipher* if the named cipher is an AEAD mode).

class AEAD_Mode

void **set_key**(**const** SymmetricKey &*key*)
Set the key

Key_Length_Specification **key_spec**() **const**
Return the key length specification

void **set_associated_data**(**const** uint8_t *ad*[], size_t *ad_len*)
Set any associated data for this message. For maximum portability between different modes, this must be called after *set_key* and before *start*.

If the associated data does not change, it is not necessary to call this function more than once, even across multiple calls to *start* and *finish*.

void **start**(**const** uint8_t *nonce*[], size_t *nonce_len*)
Start processing a message, using *nonce* as the unique per-message value. It does not need to be random, simply unique (per key).

> **Warning:** With almost all AEADs, if the same nonce is ever used to encrypt two different messages under the same key, all security is lost. If reliably generating unique nonces is difficult in your environment, use SIV mode which retains security even if nonces are repeated.

void **update**(secure_vector<uint8_t> &*buffer*, size_t *offset* = 0)
Continue processing a message. The *buffer* is an in/out parameter and may be resized. In particular, some modes require that all input be consumed before any output is produced; with these modes, *buffer* will be returned empty.

On input, the buffer must be sized in blocks of size *update_granularity*. For instance if the update granularity was 64, then *buffer* could be 64, 128, 192, ... bytes.

The first *offset* bytes of *buffer* will be ignored (this allows in place processing of a buffer that contains an initial plaintext header)

void **finish**(secure_vector<uint8_t> &*buffer*, size_t *offset* = 0)
Complete processing a message with a final input of *buffer*, which is treated the same as with *update*. It must contain at least *final_minimum_size* bytes.

Note that if you have the entire message in hand, calling finish without ever calling update is both efficient and convenient.

Note: During decryption, finish will throw an instance of Integrity_Failure if the MAC does not validate. If this occurs, all plaintext previously output via calls to update must be destroyed and not used in any way that an attacker could observe the effects of.

One simply way to assure this could never happen is to never call update, and instead always marshal the entire message into a single buffer and call finish on it when decrypting.

---

size_t **update_granularity**() **const**
The AEAD interface requires *update* be called with blocks of this size. This will be 1, if the mode can process any length inputs.

size_t **final_minimum_size**() **const**
The AEAD interface requires *finish* be called with at least this many bytes (which may be zero, or greater than *update_granularity*)

bool **valid_nonce_length**(size_t *nonce_len*) **const**
Returns true if *nonce_len* is a valid nonce length for this scheme. For EAX and GCM, any length nonces are allowed. OCB allows any value between 8 and 15 bytes.

size_t **default_nonce_length**() **const**
Returns a reasonable length for the nonce, typically either 96 bits, or the only supported length for modes which don't support 96 bit nonces.

12.4 Available AEAD Modes

If in doubt about what to use, pick ChaCha20Poly1305, AES-256/GCM, or AES-256/SIV. Both ChaCha20Poly1305 and AES with GCM are widely implemented. SIV is somewhat more obscure (and is slower than either GCM or ChaCha20Poly1305), but has excellent security properties.

12.4.1 ChaCha20Poly1305

Available if `BOTAN_HAS_AEAD_CHACHA20_POLY1305` is defined.

Unlike the other AEADs which are based on block ciphers, this mode is based on the ChaCha stream cipher and the Poly1305 authentication code. It is very fast on all modern platforms.

ChaCha20Poly1305 supports 64-bit, 96-bit, and (since 2.8) 192-bit nonces. 64-bit nonces are the "classic" ChaCha20Poly1305 design. 96-bit nonces are used by the IETF standard version of ChaCha20Poly1305. And 192-bit nonces is the XChaCha20Poly1305 construction, which is somewhat less common.

For best interop use the IETF version with 96-bit nonces. However 96 bits is small enough that it can be dangerous to generate nonces randomly if more than ~ 2^32 messages are encrypted under a single key, since if a nonce is ever reused ChaCha20Poly1305 becomes insecure. It is better to use a counter for the nonce in this case.

If you are encrypting many messages under a single key and cannot maintain a counter for the nonce, prefer XChaCha20Poly1305 since a 192 bit nonce is large enough that random values are extremely unlikely to repeat.

12.4.2 GCM

Available if `BOTAN_HAS_AEAD_GCM` is defined.

NIST standard, commonly used. Requires a 128-bit block cipher. Fairly slow, unless hardware support for carryless multiplies is available.

12.4.3 OCB

Available if `BOTAN_HAS_AEAD_OCB` is defined.

A block cipher based AEAD. Supports 128-bit, 256-bit and 512-bit block ciphers. This mode is very fast and easily secured against side channels. Adoption has been poor because it is patented in the United States, though a license is available allowing it to be freely used by open source software.

12.4.4 EAX

Available if `BOTAN_HAS_AEAD_EAX` is defined.

A secure composition of CTR mode and CMAC. Supports 128-bit, 256-bit and 512-bit block ciphers.

12.4.5 SIV

Available if `BOTAN_HAS_AEAD_SIV` is defined.

Requires a 128-bit block cipher. Unlike other AEADs, SIV is "misuse resistant"; if a nonce is repeated, SIV retains security, with the exception that if the same nonce is used to encrypt the same message multiple times, an attacker can detect the fact that the message was duplicated (this is simply because if both the nonce and the message are reused, SIV will output identical ciphertexts).

12.4.6 CCM

Available if `BOTAN_HAS_AEAD_CCM` is defined.

A composition of CTR mode and CBC-MAC. Requires a 128-bit block cipher. This is a NIST standard mode, but that is about all to recommend it. Prefer EAX.

CHAPTER

THIRTEEN

PUBLIC KEY CRYPTOGRAPHY

Public key cryptography (also called asymmetric cryptography) is a collection of techniques allowing for encryption, signatures, and key agreement.

13.1 Key Objects

Public and private keys are represented by classes `Public_Key` and it's subclass `Private_Key`. The use of inheritance here means that a `Private_Key` can be converted into a reference to a public key.

None of the functions on `Public_Key` and `Private_Key` itself are particularly useful for users of the library, because 'bare' public key operations are *very insecure*. The only purpose of these functions is to provide a clean interface that higher level operations can be built on. So really the only thing you need to know is that when a function takes a reference to a `Public_Key`, it can take any public key or private key, and similarly for `Private_Key`.

Types of `Public_Key` include `RSA_PublicKey`, `DSA_PublicKey`, `ECDSA_PublicKey`, `ECKCDSA_PublicKey`, `ECGDSA_PublicKey`, `DH_PublicKey`, `ECDH_PublicKey`, `Curve25519_PublicKey`, `ElGamal_PublicKey`, `McEliece_PublicKey`, `XMSS_PublicKey` and `GOST_3410_PublicKey`. There are corresponding `Private_Key` classes for each of these algorithms.

13.2 Creating New Private Keys

Creating a new private key requires two things: a source of random numbers (see *Random Number Generators*) and some algorithm specific parameters that define the *security level* of the resulting key. For instance, the security level of an RSA key is (at least in part) defined by the length of the public key modulus in bits. So to create a new RSA private key, you would call

RSA_PrivateKey`::`**`RSA_PrivateKey`**(*RandomNumberGenerator* &*rng*, size_t *bits*)
A constructor that creates a new random RSA private key with a modulus of length *bits*.

Algorithms based on the discrete-logarithm problem use what is called a *group*; a group can safely be used with many keys, and for some operations, like key agreement, the two keys *must* use the same group. There are currently two kinds of discrete logarithm groups supported in botan: the integers modulo a prime, represented by *DL_Group*, and elliptic curves in GF(p), represented by *EC_Group*. A rough generalization is that the larger the group is, the more secure the algorithm is, but correspondingly the slower the operations will be.

Given a `DL_Group`, you can create new DSA, Diffie-Hellman and ElGamal key pairs with

DSA_PrivateKey`::`**`DSA_PrivateKey`**(*RandomNumberGenerator* &*rng*, **`const`** DL_Group &*group*, **`const`** *BigInt* &*x* = 0)

DH_PrivateKey`::`**`DH_PrivateKey`**(*RandomNumberGenerator* &*rng*, **`const`** DL_Group &*group*, **`const`** *BigInt* &*x* = 0)

ElGamal_PrivateKey::**ElGamal_PrivateKey**(*RandomNumberGenerator* &*rng*, **const** DL_Group &*group*, **const** *BigInt* &*x* = 0)

The optional *x* parameter to each of these constructors is a private key value. This allows you to create keys where the private key is formed by some special technique; for instance you can use the hash of a password (see *Password Based Key Derivation* for how to do that) as a private key value. Normally, you would leave the value as zero, letting the class generate a new random key.

Finally, given an `EC_Group` object, you can create a new ECDSA, ECKCDSA, ECGDSA, ECDH, or GOST 34.10-2001 private key with

ECDSA_PrivateKey::**ECDSA_PrivateKey**(*RandomNumberGenerator* &*rng*, **const** *EC_Group* &*domain*, **const** *BigInt* &*x* = 0)

ECKCDSA_PrivateKey::**ECKCDSA_PrivateKey**(*RandomNumberGenerator* &*rng*, **const** *EC_Group* &*domain*, **const** *BigInt* &*x* = 0)

ECGDSA_PrivateKey::**ECGDSA_PrivateKey**(*RandomNumberGenerator* &*rng*, **const** *EC_Group* &*domain*, **const** *BigInt* &*x* = 0)

ECDH_PrivateKey::**ECDH_PrivateKey**(*RandomNumberGenerator* &*rng*, **const** *EC_Group* &*domain*, **const** *BigInt* &*x* = 0)

GOST_3410_PrivateKey::**GOST_3410_PrivateKey**(*RandomNumberGenerator* &*rng*, **const** *EC_Group* &*domain*, **const** *BigInt* &*x* = 0)

13.3 Serializing Private Keys Using PKCS #8

The standard format for serializing a private key is PKCS #8, the operations for which are defined in `pkcs8.h`. It supports both unencrypted and encrypted storage.

secure_vector<uint8_t> `PKCS8`::**BER_encode**(**const** Private_Key &*key*, *RandomNumberGenerator* &*rng*, **const** std::string &*password*, **const** std::string &*pbe_algo* = "")

Takes any private key object, serializes it, encrypts it using *password*, and returns a binary structure representing the private key.

The final (optional) argument, *pbe_algo*, specifies a particular password based encryption (or PBE) algorithm. If you don't specify a PBE, a sensible default will be used.

The currently supported PBE is PBES2 from PKCS5. Format is as follows: `PBE-PKCS5v20(CIPHER,PBKDF)`. Since 2.8.0, `PBES2(CIPHER,PBKDF)` also works. Cipher can be any block cipher with /CBC or /GCM appended, for example "AES-128/CBC" or "Camellia-256/GCM". For best interop with other systems, use AES in CBC mode. The PBKDF can be either the name of a hash function (in which case PBKDF2 is used with that hash) or "Scrypt", which causes the scrypt memory hard password hashing function to be used. Scrypt is supported since version 2.7.0.

Use *PBE-PKCS5v20(AES-256/CBC,SHA-256)* if you want to ensure the keys can be imported by different software packages. Use *PBE-PKCS5v20(AES-256/GCM,Scrypt)* for best security assuming you do not care about interop.

For ciphers you can use anything which has an OID defined for CBC, GCM or SIV modes. Currently this includes AES, Camellia, Serpent, Twofish, and SM4. Most other libraries only support CBC mode for private key encryption. GCM has been supported in PBES2 since 1.11.10. SIV has been supported since 2.8.

std::string `PKCS8`::**PEM_encode**(**const** Private_Key &*key*, *RandomNumberGenerator* &*rng*, **const** std::string &*pass*, **const** std::string &*pbe_algo* = "")

This formats the key in the same manner as `BER_encode`, but additionally encodes it into a text format with identifying headers. Using PEM encoding is *highly* recommended for many reasons, including compatibility with other software, for transmission over 8-bit unclean channels, because it can be identified by a human without special tools, and because it sometimes allows more sane behavior of tools that process the data.

Unencrypted serialization is also supported.

Warning: In most situations, using unencrypted private key storage is a bad idea, because anyone can come along and grab the private key without having to know any passwords or other secrets. Unless you have very particular security requirements, always use the versions that encrypt the key based on a passphrase, described above.

secure_vector<uint8_t> PKCS8::**BER_encode**(**const** Private_Key &*key*)
Serializes the private key and returns the result.

std::string PKCS8::**PEM_encode**(**const** Private_Key &*key*)
Serializes the private key, base64 encodes it, and returns the result.

Last but not least, there are some functions that will load (and decrypt, if necessary) a PKCS #8 private key:

Private_Key *PKCS8::**load_key**(DataSource &*in*, *RandomNumberGenerator* &*rng*, **const** User_Interface &*ui*)

Private_Key *PKCS8::**load_key**(DataSource &*in*, *RandomNumberGenerator* &*rng*, std::string *passphrase* = "")

Private_Key *PKCS8::**load_key**(**const** std::string &*filename*, *RandomNumberGenerator* &*rng*, **const** User_Interface &*ui*)

Private_Key *PKCS8::**load_key**(**const** std::string &*filename*, *RandomNumberGenerator* &*rng*, **const** std::string &*passphrase* = "")

These functions will return an object allocated key object based on the data from whatever source it is using (assuming, of course, the source is in fact storing a representation of a private key, and the decryption was successful). The encoding used (PEM or BER) need not be specified; the format will be detected automatically. The key is allocated with `new`, and should be released with `delete` when you are done with it. The first takes a generic `DataSource` that you have to create - the other is a simple wrapper functions that take either a filename or a memory buffer and create the appropriate `DataSource`.

The versions taking a `std::string` attempt to decrypt using the password given (if the key is encrypted; if it is not, the passphase value will be ignored). If the passphrase does not decrypt the key, an exception will be thrown.

The ones taking a `User_Interface` provide a simple callback interface which makes handling incorrect passphrases and such a bit simpler. A `User_Interface` has very little to do with talking to users; it's just a way to glue together Botan and whatever user interface you happen to be using.

Note: In a future version, it is likely that `User_Interface` will be replaced by a simple callback using `std::function`.

To use `User_Interface`, derive a subclass and implement:

std::string `User_Interface`::**get_passphrase**(**const** std::string &*what*, **const** std::string &*source*, UI_Result &*result*) **const**

The `what` argument specifies what the passphrase is needed for (for example, PKCS #8 key loading passes `what` as "PKCS #8 private key"). This lets you provide the user with some indication of *why* your application is asking for a passphrase; feel free to pass the string through `gettext(3)` or moral equivalent for i18n purposes. Similarly, `source` specifies where the data in question came from, if available (for example, a file name). If the source is not available for whatever reason, then `source` will be an empty string; be sure to account for this possibility.

The function returns the passphrase as the return value, and a status code in `result` (either `OK` or `CANCEL_ACTION`). If `CANCEL_ACTION` is returned in `result`, then the return value will be ignored, and the caller will take whatever action is necessary (typically, throwing an exception stating that the passphrase couldn't be determined). In the specific case of PKCS #8 key decryption, a `Decoding_Error` exception will

be thrown; your UI should assume this can happen, and provide appropriate error handling (such as putting up a dialog box informing the user of the situation, and canceling the operation in progress).

13.3.1 Serializing Public Keys

To import and export public keys, use:

std::vector<uint8_t> `X509::BER_encode`(**const** Public_Key &*key*)

std::string `X509::PEM_encode`(**const** Public_Key &*key*)

Public_Key *`X509::load_key`(DataSource &*in*)

Public_Key *`X509::load_key`(**const** secure_vector<uint8_t> &*buffer*)

Public_Key *`X509::load_key`(**const** std::string &*filename*)
These functions operate in the same way as the ones described in *Serializing Private Keys Using PKCS #8*, except that no encryption option is available.

13.3.2 DL_Group

As described in *Creating New Private Keys*, a discrete logarithm group can be shared among many keys, even keys created by users who do not trust each other. However, it is necessary to trust the entity who created the group; that is why organization like NIST use algorithms which generate groups in a deterministic way such that creating a bogus group would require breaking some trusted cryptographic primitive like SHA-2.

Instantiating a `DL_Group` simply requires calling

`DL_Group``::DL_Group`(**const** std::string &*name*)
The *name* parameter is a specially formatted string that consists of three things, the type of the group ("modp" or "dsa"), the creator of the group, and the size of the group in bits, all delimited by '/' characters.

Currently all "modp" groups included in botan are ones defined by the Internet Engineering Task Force, so the provider is "ietf", and the strings look like "modp/ietf/N" where N can be any of 1024, 1536, 2048, 3072, 4096, 6144, or 8192. This group type is used for Diffie-Hellman and ElGamal algorithms.

The other type, "dsa" is used for DSA keys. They can also be used with Diffie-Hellman and ElGamal, but this is less common. The currently available groups are "dsa/jce/1024" and "dsa/botan/N" with N being 2048 or 3072. The "jce" groups are the standard DSA groups used in the Java Cryptography Extensions, while the "botan" groups were randomly generated using the FIPS 186-3 algorithm by the library maintainers.

You can generate a new random group using

`DL_Group``::DL_Group`(*RandomNumberGenerator* &*rng*, PrimeType *type*, size_t *pbits*, size_t *qbits* = 0)
The *type* can be either `Strong`, `Prime_Subgroup`, or `DSA_Kosherizer`. *pbits* specifies the size of the prime in bits. If the *type* is `Prime_Subgroup` or `DSA_Kosherizer`, then *qbits* specifies the size of the subgroup.

You can serialize a `DL_Group` using

secure_vector<uint8_t> `DL_Group::DER_Encode`(Format *format*)

or

std::string `DL_Group::PEM_encode`(Format *format*)

where *format* is any of

- `ANSI_X9_42` (or `DH_PARAMETERS`) for modp groups
- `ANSI_X9_57` (or `DSA_PARAMETERS`) for DSA-style groups

- PKCS_3 is an older format for modp groups; it should only be used for backwards compatibility.

You can reload a serialized group using

void DL_Group::**BER_decode**(DataSource &*source*, Format *format*)

void DL_Group::**PEM_decode**(DataSource &*source*)

Code Example

The example below creates a new 2048 bit DL_Group, prints the generated parameters and ANSI_X9_42 encodes the created group for further usage with DH.

```
#include <botan/dl_group.h>
#include <botan/auto_rng.h>
#include <botan/rng.h>
#include <iostream>

int main()
   {
      std::unique_ptr<Botan::RandomNumberGenerator> rng(new Botan::AutoSeeded_RNG);
      std::unique_ptr<Botan::DL_Group> group(new Botan::DL_Group(*rng.get(),␣
↪Botan::DL_Group::Strong, 2048));
      std::cout << std::endl << "p: " << group->get_p();
      std::cout << std::endl << "q: " << group->get_q();
      std::cout << std::endl << "g: " << group->get_q();
      std::cout << std::endl << "ANSI_X9_42: " << std::endl << group->PEM_
↪encode(Botan::DL_Group::ANSI_X9_42);

    return 0;
   }
```

13.3.3 EC_Group

An EC_Group is initialized by passing the name of the group to be used to the constructor. These groups have semi-standardized names like "secp256r1" and "brainpool512r1".

13.4 Key Checking

Most public key algorithms have limitations or restrictions on their parameters. For example RSA requires an odd exponent, and algorithms based on the discrete logarithm problem need a generator > 1.

Each public key type has a function

bool Public_Key::**check_key**(*RandomNumberGenerator* &*rng*, bool *strong*)

This function performs a number of algorithm-specific tests that the key seems to be mathematically valid and consistent, and returns true if all of the tests pass.

It does not have anything to do with the validity of the key for any particular use, nor does it have anything to do with certificates that link a key (which, after all, is just some numbers) with a user or other entity. If *strong* is true, then it does "strong" checking, which includes expensive operations like primality checking.

As key checks are not automatically performed they must be called manually after loading keys from untrusted sources. If a key from an untrusted source is not checked, the implementation might be vulnerable to algorithm specific attacks.

The following example loads the Subject Public Key from the x509 certificate `cert.pem` and checks the loaded key. If the key check fails a respective error is thrown.

```
#include <botan/x509cert.h>
#include <botan/auto_rng.h>
#include <botan/rng.h>

int main()
   {
   Botan::X509_Certificate cert("cert.pem");
   std::unique_ptr<Botan::RandomNumberGenerator> rng(new Botan::AutoSeeded_RNG);
   std::unique_ptr<Botan::Public_Key> key(cert.subject_public_key());
   if(!key->check_key(*rng.get(), false))
      {
      throw std::invalid_argument("Loaded key is invalid");
      }
   }
```

13.5 Encryption

Safe public key encryption requires the use of a padding scheme which hides the underlying mathematical properties of the algorithm. Additionally, they will add randomness, so encrypting the same plaintext twice produces two different ciphertexts.

The primary interface for encryption is

class PK_Encryptor

secure_vector<uint8_t> **encrypt**(**const** uint8_t *in, size_t *length*, *RandomNumberGenerator* &*rng*) **const**

secure_vector<uint8_t> **encrypt**(**const** std::vector<uint8_t> &*in*, *RandomNumberGenerator* &*rng*) **const**

These encrypt a message, returning the ciphertext.

size_t **maximum_input_size**() **const**

Returns the maximum size of the message that can be processed, in bytes. If you call *PK_Encryptor::encrypt* with a value larger than this the operation will fail with an exception.

PK_Encryptor is only an interface - to actually encrypt you have to create an implementation, of which there are currently three available in the library, *PK_Encryptor_EME*, *DLIES_Encryptor* and *ECIES_Encryptor*. DLIES is a hybrid encryption scheme (from IEEE 1363) that uses the DH key agreement technique in combination with a KDF, a MAC and a symmetric encryption algorithm to perform message encryption. ECIES is similar to DLIES, but uses ECDH for the key agreement. Normally, public key encryption is done using algorithms which support it directly, such as RSA or ElGamal; these use the EME class:

class PK_Encryptor_EME

PK_Encryptor_EME(**const** Public_Key &*key*, std::string *eme*)

With *key* being the key you want to encrypt messages to. The padding method to use is specified in *eme*.

The recommended values for *eme* is "EME1(SHA-1)" or "EME1(SHA-256)". If you need compatibility with protocols using the PKCS #1 v1.5 standard, you can also use "EME-PKCS1-v1_5".

class DLIES_Encryptor

Available in the header `dlies.h`

DLIES_Encryptor(**const** DH_PrivateKey &*own_priv_key*, *RandomNumberGenerator* &*rng*, *KDF* **kdf*, *MessageAuthenticationCode* **mac*, size_t *mac_key_len* = 20)

Where *kdf* is a key derivation function (see *Key Derivation Functions*) and *mac* is a MessageAuthenticationCode. The encryption is performed by XORing the message with a stream of bytes provided by the KDF.

DLIES_Encryptor(**const** DH_PrivateKey &*own_priv_key*, *RandomNumberGenerator* &*rng*, *KDF* **kdf*, *Cipher_Mode* **cipher*, size_t *cipher_key_len*, *MessageAuthenticationCode* **mac*, size_t *mac_key_len* = 20)

Instead of XORing the message a block cipher can be specified.

class ECIES_Encryptor

Available in the header `ecies.h`.

Parameters for encryption and decryption are set by the `ECIES_System_Params` class which stores the EC domain parameters, the KDF (see *Key Derivation Functions*), the cipher (see *Cipher Modes*) and the MAC.

ECIES_Encryptor(**const** PK_Key_Agreement_Key &*private_key*, **const** ECIES_System_Params &*ecies_params*, *RandomNumberGenerator* &*rng*)

Where *private_key* is the key to use for the key agreement. The system parameters are specified in *ecies_params* and the RNG to use is passed in *rng*.

ECIES_Encryptor(*RandomNumberGenerator* &*rng*, **const** ECIES_System_Params &*ecies_params*)

Creates an ephemeral private key which is used for the key agreement.

The decryption classes are named `PK_Decryptor`, `PK_Decryptor_EME`, `DLIES_Decryptor` and `ECIES_Decryptor`. They are created in the exact same way, except they take the private key, and the processing function is named `decrypt`.

Botan implements the following encryption algorithms and padding schemes:

1. **RSA**
   - "PKCS1v15" || "EME-PKCS1-v1_5"
   - "OAEP" || "EME-OAEP" || "EME1" || "EME1(SHA-1)" || "EME1(SHA-256)"
2. DLIES
3. ECIES
4. SM2

13.5.1 Code Example

The following Code sample reads a PKCS #8 keypair from the passed location and subsequently encrypts a fixed plaintext with the included public key, using EME1 with SHA-256. For the sake of completeness, the ciphertext is then decrypted using the private key.

```
#include <botan/pkcs8.h>
#include <botan/hex.h>
#include <botan/pk_keys.h>
#include <botan/pubkey.h>
#include <botan/auto_rng.h>
#include <botan/rng.h>
#include <iostream>
int main (int argc, char* argv[])
  {
  if(argc!=2)
     return 1;
```

(continues on next page)

(continued from previous page)

```
  std::string plaintext("Your great-grandfather gave this watch to your granddad for␣
↪good luck. Unfortunately, Dane's luck wasn't as good as his old man's.");
  std::vector<uint8_t> pt(plaintext.data(),plaintext.data()+plaintext.length());
  std::unique_ptr<Botan::RandomNumberGenerator> rng(new Botan::AutoSeeded_RNG);

  //load keypair
  std::unique_ptr<Botan::Private_Key> kp(Botan::PKCS8::load_key(argv[1],*rng.get()));

  //encrypt with pk
  Botan::PK_Encryptor_EME enc(*kp,*rng.get(), "EME1(SHA-256)");
  std::vector<uint8_t> ct = enc.encrypt(pt,*rng.get());

  //decrypt with sk
  Botan::PK_Decryptor_EME dec(*kp,*rng.get(), "EME1(SHA-256)");
  std::cout << std::endl << "enc: " << Botan::hex_encode(ct) << std::endl << "dec: "<
↪< Botan::hex_encode(dec.decrypt(ct));

  return 0;
  }
```

13.6 Signatures

Signature generation is performed using

class PK_Signer

PK_Signer(**const** Private_Key &*key*, **const** std::string &*emsa*, Signature_Format *format* = IEEE_1363)

Constructs a new signer object for the private key *key* using the signature format *emsa*. The key must support signature operations. In the current version of the library, this includes RSA, DSA, ECDSA, ECKCDSA, ECGDSA, GOST 34.10-2001. Other signature schemes may be supported in the future.

Note: Botan both supports non-deterministic and deterministic (as per RFC 6979) DSA and ECDSA signatures. Deterministic signatures are compatible in the way that they can be verified with a non-deterministic implementation. If the `rfc6979` module is enabled, deterministic DSA and ECDSA signatures will be generated.

Currently available values for *emsa* include EMSA1, EMSA2, EMSA3, EMSA4, and Raw. All of them, except Raw, take a parameter naming a message digest function to hash the message with. The Raw encoding signs the input directly; if the message is too big, the signing operation will fail. Raw is not useful except in very specialized applications. Examples are "EMSA1(SHA-1)" and "EMSA4(SHA-256)".

For RSA, use EMSA4 (also called PSS) unless you need compatibility with software that uses the older PKCS #1 v1.5 standard, in which case use EMSA3 (also called "EMSA-PKCS1-v1_5"). For DSA, ECDSA, ECKCDSA, ECGDSA and GOST 34.10-2001 you should use EMSA1.

The *format* defaults to `IEEE_1363` which is the only available format for RSA. For DSA, ECDSA, ECGDSA and ECKCDSA you can also use `DER_SEQUENCE`, which will format the signature as an ASN.1 SEQUENCE value.

void **update**(**const** uint8_t **in*, size_t *length*)

void **update**(**const** std::vector<uint8_t> &*in*)

void **update**(uint8_t *in*)
These add more data to be included in the signature computation. Typically, the input will be provided directly to a hash function.

secure_vector<uint8_t> **signature**(*RandomNumberGenerator* &*rng*)
Creates the signature and returns it

secure_vector<uint8_t> **sign_message**(**const** uint8_t **in*, size_t *length*, *RandomNumberGenerator* &*rng*)

secure_vector<uint8_t> **sign_message**(**const** std::vector<uint8_t> &*in*, *RandomNumberGenerator* &*rng*)
These functions are equivalent to calling `PK_Signer::update` and then `PK_Signer::signature`. Any data previously provided using `update` will be included.

Signatures are verified using

class PK_Verifier

PK_Verifier(**const** Public_Key &*pub_key*, **const** std::string &*emsa*, Signature_Format *format* = IEEE_1363)
Construct a new verifier for signatures associated with public key *pub_key*. The *emsa* and *format* should be the same as that used by the signer.

void **update**(**const** uint8_t **in*, size_t *length*)

void **update**(**const** std::vector<uint8_t> &*in*)

void **update**(uint8_t *in*)
Add further message data that is purportedly associated with the signature that will be checked.

bool **check_signature**(**const** uint8_t **sig*, size_t *length*)

bool **check_signature**(**const** std::vector<uint8_t> &*sig*)
Check to see if *sig* is a valid signature for the message data that was written in. Return true if so. This function clears the internal message state, so after this call you can call `PK_Verifier::update` to start verifying another message.

bool **verify_message**(**const** uint8_t **msg*, size_t *msg_length*, **const** uint8_t **sig*, size_t *sig_length*)

bool **verify_message**(**const** std::vector<uint8_t> &*msg*, **const** std::vector<uint8_t> &*sig*)
These are equivalent to calling `PK_Verifier::update` on *msg* and then calling `PK_Verifier::check_signature` on *sig*.

Botan implements the following signature algorithms:

1. RSA
2. DSA
3. ECDSA
4. ECGDSA
5. ECKDSA
6. GOST 34.10-2001
7. Ed25519
8. SM2

13.6.1 Code Example

The following sample program below demonstrates the generation of a new ECDSA keypair over the curve secp512r1 and a ECDSA signature using EMSA1 with SHA-256. Subsequently the computed signature is validated.

```
#include <botan/auto_rng.h>
#include <botan/ecdsa.h>
#include <botan/ec_group.h>
#include <botan/pubkey.h>
#include <botan/hex.h>
#include <iostream>

int main()
  {
  Botan::AutoSeeded_RNG rng;
  // Generate ECDSA keypair
  Botan::ECDSA_PrivateKey key(rng, Botan::EC_Group("secp521r1"));

  std::string text("This is a tasty burger!");
  std::vector<uint8_t> data(text.data(),text.data()+text.length());
  // sign data
  Botan::PK_Signer signer(key, rng, "EMSA1(SHA-256)");
  signer.update(data);
  std::vector<uint8_t> signature = signer.signature(rng);
  std::cout << "Signature:" << std::endl << Botan::hex_encode(signature);
  // verify signature
  Botan::PK_Verifier verifier(key, "EMSA1(SHA-256)");
  verifier.update(data);
  std::cout << std::endl << "is " << (verifier.check_signature(signature)? "valid" :
↪"invalid");
  return 0;
  }
```

13.7 Key Agreement

You can get a hold of a `PK_Key_Agreement_Scheme` object by calling `get_pk_kas` with a key that is of a type that supports key agreement (such as a Diffie-Hellman key stored in a `DH_PrivateKey` object), and the name of a key derivation function. This can be "Raw", meaning the output of the primitive itself is returned as the key, or "KDF1(hash)" or "KDF2(hash)" where "hash" is any string you happen to like (hopefully you like strings like "SHA-256" or "RIPEMD-160"), or "X9.42-PRF(keywrap)", which uses the PRF specified in ANSI X9.42. It takes the name or OID of the key wrap algorithm that will be used to encrypt a content encryption key.

How key agreement works is that you trade public values with some other party, and then each of you runs a computation with the other's value and your key (this should return the same result to both parties). This computation can be called by using `derive_key` with either a byte array/length pair, or a `secure_vector<uint8_t>` than holds the public value of the other party. The last argument to either call is a number that specifies how long a key you want.

Depending on the KDF you're using, you *might not* get back a key of the size you requested. In particular "Raw" will return a number about the size of the Diffie-Hellman modulus, and KDF1 can only return a key that is the same size as the output of the hash. KDF2, on the other hand, will always give you a key exactly as long as you request, regardless of the underlying hash used with it. The key returned is a `SymmetricKey`, ready to pass to a block cipher, MAC, or other symmetric algorithm.

The public value that should be used can be obtained by calling `public_data`, which exists for any key that is associated with a key agreement algorithm. It returns a `secure_vector<uint8_t>`.

"KDF2(SHA-256)" is by far the preferred algorithm for key derivation in new applications. The X9.42 algorithm may be useful in some circumstances, but unless you need X9.42 compatibility, KDF2 is easier to use.

Botan implements the following key agreement methods:

1. ECDH over GF(p) Weierstrass curves
2. ECDH over x25519
3. DH over prime fields
4. McEliece
5. NewHope

13.7.1 Code Example

The code below performs an unauthenticated ECDH key agreement using the secp521r elliptic curve and applies the key derivation function KDF2(SHA-256) with 256 bit output length to the computed shared secret.

```
#include <botan/auto_rng.h>
#include <botan/ecdh.h>
#include <botan/ec_group.h>
#include <botan/pubkey.h>
#include <botan/hex.h>
#include <iostream>

int main()
   {
   Botan::AutoSeeded_RNG rng;
   // ec domain and
   Botan::EC_Group domain("secp521r1");
   std::string kdf = "KDF2(SHA-256)";
   // generate ECDH keys
   Botan::ECDH_PrivateKey keyA(rng, domain);
   Botan::ECDH_PrivateKey keyB(rng, domain);
   // Construct key agreements
   Botan::PK_Key_Agreement ecdhA(keyA,rng,kdf);
   Botan::PK_Key_Agreement ecdhB(keyB,rng,kdf);
   // Agree on shared secret and derive symmetric key of 256 bit length
   Botan::secure_vector<uint8_t> sA = ecdhA.derive_key(32,keyB.public_value()).bits_
↪of();
   Botan::secure_vector<uint8_t> sB = ecdhB.derive_key(32,keyA.public_value()).bits_
↪of();

   if(sA != sB)
      return 1;

   std::cout << "agreed key: " << std::endl << Botan::hex_encode(sA);
   return 0;
   }
```

13.8 McEliece

McEliece is a cryptographic scheme based on error correcting codes which is thought to be resistant to quantum computers. First proposed in 1978, it is fast and patent-free. Variants have been proposed and broken, but with

suitable parameters the original scheme remains secure. However the public keys are quite large, which has hindered deployment in the past.

The implementation of McEliece in Botan was contributed by cryptosource GmbH. It is based on the implementation HyMES, with the kind permission of Nicolas Sendrier and INRIA to release a C++ adaption of their original C code under the Botan license. It was then modified by Falko Strenzke to add side channel and fault attack countermeasures. You can read more about the implementation at http://www.cryptosource.de/docs/mceliece_in_botan.pdf

Encryption in the McEliece scheme consists of choosing a message block of size n, encoding it in the error correcting code which is the public key, then adding t bit errors. The code is created such that knowing only the public key, decoding t errors is intractable, but with the additional knowledge of the secret structure of the code a fast decoding technique exists.

The McEliece implementation in HyMES, and also in Botan, uses an optimization to reduce the public key size, by converting the public key into a systemic code. This means a portion of the public key is a identity matrix, and can be excluded from the published public key. However it also means that in McEliece the plaintext is represented directly in the ciphertext, with only a small number of bit errors. Thus it is absolutely essential to only use McEliece with a CCA2 secure scheme.

One such scheme, KEM, is provided in Botan currently. It it a somewhat unusual scheme in that it outputs two values, a symmetric key for use with an AEAD, and an encrypted key. It does this by choosing a random plaintext (n - log2(n)*t bits) using `McEliece_PublicKey::random_plaintext_element`. Then a random error mask is chosen and the message is coded and masked. The symmetric key is SHA-512(plaintext || error_mask). As long as the resulting key is used with a secure AEAD scheme (which can be used for transporting arbitrary amounts of data), CCA2 security is provided.

In `mcies.h` there are functions for this combination:

secure_vector<uint8_t> **mceies_encrypt**(**const** McEliece_PublicKey &*pubkey*, **const** secure_vector<uint8_t> &*pt*, uint8_t *ad*[], size_t *ad_len*, *RandomNumberGenerator* &*rng*, **const** std::string &*aead* = "AES-256/OCB")

secure_vector<uint8_t> **mceies_decrypt**(**const** McEliece_PrivateKey &*privkey*, **const** secure_vector<uint8_t> &*ct*, uint8_t *ad*[], size_t *ad_len*, **const** std::string &*aead* = "AES-256/OCB")

For a given security level (SL) a McEliece key would use parameters n and t, and have the corresponding key sizes listed:

SL	n	t	public key KB	private key KB
80	1632	33	59	140
107	2280	45	128	300
128	2960	57	195	459
147	3408	67	265	622
191	4624	95	516	1234
256	6624	115	942	2184

You can check the speed of McEliece with the suggested parameters above using `botan speed McEliece`

13.9 eXtended Merkle Signature Scheme (XMSS)

Botan implements the single tree version of the eXtended Merkle Signature Scheme (XMSS) using Winternitz One Time Signatures+ (WOTS+). The implementation is based on IETF Internet-Draft "XMSS: Extended Hash-Based Signatures".

XMSS uses the Botan interfaces for public key cryptography. The following algorithms are implemented:

1. XMSS_SHA2-256_W16_H10
2. XMSS_SHA2-256_W16_H16
3. XMSS_SHA2-256_W16_H20
4. XMSS_SHA2-512_W16_H10
5. XMSS_SHA2-512_W16_H16
6. XMSS_SHA2-512_W16_H20
7. XMSS_SHAKE128_W16_H10
8. XMSS_SHAKE128_W16_H10
9. XMSS_SHAKE128_W16_H10
10. XMSS_SHAKE256_W16_H10
11. XMSS_SHAKE256_W16_H10
12. XMSS_SHAKE256_W16_H10

13.9.1 Code Example

The following code snippet shows a minimum example on how to create an XMSS public/private key pair and how to use these keys to create and verify a signature:

```
#include <botan/botan.h>
#include <botan/auto_rng.h>
#include <botan/xmss.h>

int main()
   {
   // Create a random number generator used for key generation.
   Botan::AutoSeeded_RNG rng;

   // create a new public/private key pair using SHA2 256 as hash
   // function and a tree height of 10.
   Botan::XMSS_PrivateKey private_key(
      Botan::XMSS_Parameters::xmss_algorithm_t::XMSS_SHA2_256_W16_H10,
      rng);
   Botan::XMSS_PublicKey public_key(private_key);

   // create signature operation using the private key.
   std::unique_ptr<Botan::PK_Ops::Signature> sig_op =
      private_key.create_signature_op(rng, "", "");

   // create and sign a message using the signature operation.
   Botan::secure_vector<uint8_t> msg { 0x01, 0x02, 0x03, 0x04 };
   sig_op->update(msg.data(), msg.size());
   Botan::secure_vector<uint8_t> sig = sig_op->sign(rng);

   // create verification operation using the public key
   std::unique_ptr<Botan::PK_Ops::Verification> ver_op =
      public_key.create_verification_op("", "");

   // verify the signature for the previously generated message.
   ver_op->update(msg.data(), msg.size());
   if(ver_op->is_valid_signature(sig.data(), sig.size()))
```

(continues on next page)

(continued from previous page)

```
      {
      std::cout << "Success." << std::endl;
      }
   else
      {
      std::cout << "Error." << std::endl;
      }
   }
```

CHAPTER

FOURTEEN

X.509 CERTIFICATES AND CRLS

A certificate is a binding between some identifying information (called a *subject*) and a public key. This binding is asserted by a signature on the certificate, which is placed there by some authority (the *issuer*) that at least claims that it knows the subject named in the certificate really "owns" the private key corresponding to the public key in the certificate.

The major certificate format in use today is X.509v3, used for instance in the *Transport Layer Security (TLS)* protocol. A X.509 certificate is represented by the class `X509_Certificate`. The data of an X.509 certificate is stored as a `shared_ptr` to a structure containing the decoded information. So copying `X509_Certificate` objects is quite cheap.

class X509_Certificate

X509_Certificate(**const** std::string &*filename*)
Load a certificate from a file. PEM or DER is accepted.

X509_Certificate(**const** std::vector<uint8_t> &*in*)
Load a certificate from a byte string.

X509_Certificate(DataSource &*source*)
Load a certificate from an abstract `DataSource`.

X509_DN **subject_dn**() **const**
Returns the distinguished name (DN) of the certificate's subject. This is the primary place where information about the subject of the certificate is stored. However "modern" information that doesn't fit in the X.500 framework, such as DNS name, email, IP address, or XMPP address, appears instead in the subject alternative name.

X509_DN **issuer_dn**() **const**
Returns the distinguished name (DN) of the certificate's issuer, ie the CA that issued this certificate.

const AlternativeName &**subject_alt_name**() **const**
Return the subjects alternative name. This is used to store values like associated URIs, DNS addresses, and email addresses.

const AlternativeName &**issuer_alt_name**() **const**
Return alternative names for the issuer.

std::unique_ptr<Public_Key> **load_subject_public_key**() **const**
Deserialize the stored public key and return a new object. This might throw, if it happens that the public key object stored in the certificate is malformed in some way, or in the case that the public key algorithm used is not supported by the library.

See *Serializing Public Keys* for more information about what to do with the returned object. It may be any type of key, in principle, though RSA and ECDSA are most common.

std::vector<uint8_t> **subject_public_key_bits**() **const**
Return the binary encoding of the subject public key. This value (or a hash of it) is used in various protocols, eg for public key pinning.

AlgorithmIdentifier **subject_public_key_algo**() **const**
Return an algorithm identifier that identifies the algorithm used in the subject's public key.

std::vector<uint8_t> **serial_number**() **const**
Return the certificates serial number. The tuple of issuer DN and serial number should be unique.

std::vector<uint8> **raw_subject_dn**() **const**
Return the binary encoding of the subject DN.

std::vector<uint8> **raw_issuer_dn**() **const**
Return the binary encoding of the issuer DN.

X509_Time **not_before**() **const**
Returns the point in time the certificate becomes valid

X509_Time **not_after**() **const**
Returns the point in time the certificate expires

const *Extensions* &**v3_extensions**() **const**
Returns all extensions of this certificate. You can use this to examine any extension data associated with the certificate, including custom extensions the library doesn't know about.

std::vector<uint8_t> **authority_key_id**() **const**
Return the authority key id, if set. This is an arbitrary string; in the issuing certificate this will be the subject key id.

std::vector<uint8_t> **subject_key_id**() **const**
Return the subject key id, if set.

bool **allowed_extended_usage**(**const** OID *&usage*) **const**
Return true if and only if the usage OID appears in the extended key usage extension. Also will return true if the extended key usage extension is not used in the current certificate.

std::string **fingerprint**(**const** std::string *&hash_fn* = "SHA-1") **const**
Return a fingerprint for the certificate, which is basically just a hash of the binary contents. Normally SHA-1 or SHA-256 is used, but any hash function is allowed.

Key_Constraints **constraints**() **const**
Returns either an enumeration listing key constraints (what the associated key can be used for) or `NO_CONSTRAINTS` if the relevant extension was not included. Example values are `DIGITAL_SIGNATURE` and `KEY_CERT_SIGN`. More than one value might be specified.

bool **matches_dns_name**(**const** std::string *&name*) **const**
Check if the certificate's subject alternative name DNS fields match `name`. This function also handles wildcard certificates.

std::string **to_string**() **const**
Returns a free-form human readable string describing the certificate.

14.1 X.509 Distinguished Names

class X509_DN

bool **has_field**(**const** std::string *&attr*) **const**
Returns true if `get_attribute` or `get_first_attribute` will return a value.

std::vector<std::string> **get_attribute**(**const** std::string &*attr*) **const**
Return all attributes associated with a certain attribute type.

std::string **get_first_attribute**(**const** std::string &*attr*) **const**
Like `get_attribute` but returns just the first attribute, or empty if the DN has no attribute of the specified type.

std::multimap<OID, std::string> **get_attributes**() **const**
Get all attributes of the DN. The OID maps to a DN component such as 2.5.4.10 ("Organization"), and the strings are UTF-8 encoded.

std::multimap<std::string, std::string> **contents**() **const**
Similar to `get_attributes`, but the OIDs are decoded to strings.

void **add_attribute**(**const** std::string &*key*, **const** std::string &*val*)
Add an attribute to a DN.

void **add_attribute**(**const** OID &*oid*, **const** std::string &*val*)
Add an attribute to a DN using an OID instead of string-valued attribute type.

The `X509_DN` type also supports iostream extraction and insertion operators, for formatted input and output.

14.2 X.509v3 Extensions

X.509v3 specifies a large number of possible extensions. Botan supports some, but by no means all of them. The following listing lists which X.509v3 extensions are supported and notes areas where there may be problems with the handling.

- Key Usage and Extended Key Usage: No problems known.
- Basic Constraints: No problems known. A self-signed v1 certificate is assumed to be a CA, while a v3 certificate is marked as a CA if and only if the basic constraints extension is present and set for a CA cert.
- Subject Alternative Names: Only the "rfc822Name", "dNSName", and "uniformResourceIdentifier" and raw IPv4 fields will be stored; all others are ignored.
- Issuer Alternative Names: Same restrictions as the Subject Alternative Names extension. New certificates generated by Botan never include the issuer alternative name.
- Authority Key Identifier: Only the version using KeyIdentifier is supported. If the GeneralNames version is used and the extension is critical, an exception is thrown. If both the KeyIdentifier and GeneralNames versions are present, then the KeyIdentifier will be used, and the GeneralNames ignored.
- Subject Key Identifier: No problems known.
- Name Constraints: No problems known (though encoding is not supported).

Any unknown critical extension in a certificate will lead to an exception during path validation.

Extensions are handled by a special class taking care of encoding and decoding. It also supports encoding and decoding of custom extensions. To do this, it internally keeps two lists of extensions. Different lookup functions are provided to search them.

Note: Validation of custom extensions during path validation is currently not supported.

---

class Extensions

void **add**(Certificate_Extension **extn*, bool *critical* = false)
Adds a new extension to the extensions object. If an extension of the same type already exists, `extn` will replace it. If `critical` is true the extension will be marked as critical in the encoding.

bool **add_new**(Certificate_Extension **extn*, bool *critical* = false)
Like `add` but an existing extension will not be replaced. Returns true if the extension was used, false if an extension of the same type was already in place.

void **replace**(Certificate_Extension **extn*, bool *critical* = false)
Adds an extension to the list or replaces it, if the same extension was already added

std::unique_ptr<Certificate_Extension> **get**(**const** OID *&oid*) **const**
Searches for an extension by OID and returns the result

template<typename **T**>
std::unique_ptr<*T*> **get_raw**(**const** OID *&oid*)
Searches for an extension by OID and returns the result. Only the unknown extensions, that is, extensions types that are not listed above, are searched for by this function.

std::vector<std::pair<std::unique_ptr<Certificate_Extension>, bool>> **extensions**() **const**
Returns the list of extensions together with the corresponding criticality flag. Only contains the supported extension types listed above.

std::map<OID, std::pair<std::vector<uint8_t>, bool>> **extensions_raw**() **const**
Returns the list of extensions as raw, encoded bytes together with the corresponding criticality flag. Contains all extensions, known as well as unknown extensions.

14.3 Certificate Revocation Lists

It will occasionally happen that a certificate must be revoked before its expiration date. Examples of this happening include the private key being compromised, or the user to which it has been assigned leaving an organization. Certificate revocation lists are an answer to this problem (though online certificate validation techniques are starting to become somewhat more popular). Every once in a while the CA will release a new CRL, listing all certificates that have been revoked. Also included is various pieces of information like what time a particular certificate was revoked, and for what reason. In most systems, it is wise to support some form of certificate revocation, and CRLs handle this easily.

For most users, processing a CRL is quite easy. All you have to do is call the constructor, which will take a filename (or a `DataSource&`). The CRLs can either be in raw BER/DER, or in PEM format; the constructor will figure out which format without any extra information. For example:

```
X509_CRL crl1("crl1.der");

DataSource_Stream in("crl2.pem");
X509_CRL crl2(in);
```

After that, pass the `X509_CRL` object to a `Certificate_Store` object with

void `Certificate_Store::`**add_crl**(**const** X509_CRL *&crl*)

and all future verifications will take into account the provided CRL.

14.3.1 Certificate Stores

An object of type `Certificate_Store` is a generalized interface to an external source for certificates (and CRLs). Examples of such a store would be one that looked up the certificates in a SQL database, or by contacting a CGI script

running on a HTTP server. There are currently three mechanisms for looking up a certificate, and one for retrieving CRLs. By default, most of these mechanisms will return an empty `std::shared_ptr` of `X509_Certificate`. This storage mechanism is *only* queried when doing certificate validation: it allows you to distribute only the root key with an application, and let some online method handle getting all the other certificates that are needed to validate an end entity certificate. In particular, the search routines will not attempt to access the external database.

The certificate lookup methods are `find_cert` (by Subject Distinguished Name and optional Subject Key Identifier) and `find_cert_by_pubkey_sha1` (by SHA-1 hash of the certificate's public key). The Subject Distinguished Name is given as a `X509_DN`, while the SKID parameter takes a `std::vector<uint8_t>` containing the subject key identifier in raw binary. Both lookup methods are mandatory to implement.

Finally, there is a method for finding a CRL, called `find_crl_for`, that takes an `X509_Certificate` object, and returns a `std::shared_ptr` of `X509_CRL`. The `std::shared_ptr` return type makes it easy to return no CRLs by returning `nullptr` (eg, if the certificate store doesn't support retrieving CRLs). Implementing the function is optional, and by default will return `nullptr`.

Certificate stores are used in the *Transport Layer Security (TLS)* module to store a list of trusted certificate authorities.

14.4 In Memory Certificate Store

The in memory certificate store keeps all objects in memory only. Certificates can be loaded from disk initially, but also added later.

class Certificate_Store_In_Memory

Certificate_Store_In_Memory(**const** std::string &*dir*)
Attempt to parse all files in `dir` (including subdirectories) as certificates. Ignores errors.

Certificate_Store_In_Memory(**const** *X509_Certificate* &*cert*)
Adds given certificate to the store

Certificate_Store_In_Memory()
Create an empty store

void **add_certificate**(**const** *X509_Certificate* &*cert*)
Add a certificate to the store

void **add_certificate**(std::shared_ptr<**const** *X509_Certificate*> *cert*)
Add a certificate already in a shared_ptr to the store

void **add_crl**(**const** X509_CRL &*crl*)
Add a certificate revocation list (CRL) to the store.

void **add_crl**(std::shared_ptr<**const** X509_CRL> *crl*)
Add a certificate revocation list (CRL) to the store as a shared_ptr

14.5 SQL-backed Certificate Stores

The SQL-backed certificate stores store all objects in an SQL database. They also additionally provide private key storage and revocation of individual certificates.

class Certificate_Store_In_SQL

Certificate_Store_In_SQL(**const** std::shared_ptr<SQL_Database> *db*, **const** std::string &*passwd*, *RandomNumberGenerator* &*rng*, **const** std::string &*table_prefix* = "")

Create or open an existing certificate store from an SQL database. The password in `passwd` will be used to encrypt private keys.

bool **insert_cert**(**const** *X509_Certificate* &*cert*)

Inserts `cert` into the store. Returns *false* if the certificate is already known and *true* if insertion was successful.

remove_cert(**const** *X509_Certificate* &*cert*)

Removes `cert` from the store. Returns *false* if the certificate could not be found and *true* if removal was successful.

std::shared_ptr<**const** Private_Key> **find_key**(**const** *X509_Certificate*&) **const**

Returns the private key for "cert" or an empty shared_ptr if none was found

std::vector<std::shared_ptr<**const** *X509_Certificate*>> **find_certs_for_key**(**const** Private_Key &*key*) **const**

Returns all certificates for private key `key`

bool **insert_key**(**const** *X509_Certificate* &*cert*, **const** Private_Key &*key*)

Inserts `key` for `cert` into the store, returns *false* if the key is already known and *true* if insertion was successful.

void **remove_key**(**const** Private_Key &*key*)

Removes `key` from the store

void **revoke_cert**(**const** *X509_Certificate*&, CRL_Code, **const** X509_Time &*time* = X509_Time())

Marks `cert` as revoked starting from `time`

void **affirm_cert**(**const** *X509_Certificate*&)

Reverses the revocation for `cert`

std::vector<X509_CRL> **generate_crls**() **const**

Generates CRLs for all certificates marked as revoked. A CRL is returned for each unique issuer DN.

The `Certificate_Store_In_SQL` class operates on an abstract `SQL_Database` object. If support for sqlite3 was enabled at build time, Botan includes an implementation of this interface for sqlite3, and a subclass of `Certificate_Store_In_SQL` which creates or opens a sqlite3 database.

class Certificate_Store_In_SQLite

Certificate_Store_In_SQLite(**const** std::string &*db_path*, **const** std::string &*passwd*, *RandomNumberGenerator* &*rng*, **const** std::string &*table_prefix* = "")

Create or open an existing certificate store from an sqlite database file. The password in `passwd` will be used to encrypt private keys.

14.5.1 Path Validation

The process of validating a certificate chain up to a trusted root is called *path validation*, and in botan that operation is handled by a set of functions in `x509path.h` named `x509_path_validate`:

Path_Validation_Result **x509_path_validate**(**const** *X509_Certificate* &*end_cert*, **const** *Path_Validation_Restrictions* &*restrictions*, **const** Certificate_Store &*store*, **const** std::string &*hostname* = "", Usage_Type *usage* = Usage_Type::UNSPECIFIED, std::chrono::system_clock::time_point *validation_time* = std::chrono::system_clock::now(), std::chrono::milliseconds *ocsp_timeout* = std::chrono::milliseconds(0), **const** std::vector<std::shared_ptr<**const** OCSP::*Response*>> &*ocsp_resp* = std::vector<std::shared_ptr<**const** OCSP::*Response*>>())

The last five parameters are optional. `hostname` specifies a hostname which is matched against the subject DN in `end_cert` according to RFC 6125. An empty hostname disables hostname validation. `usage` specifies key usage restrictions that are compared to the key usage fields in *end_cert* according to RFC 5280, if not set to `UNSPECIFIED`. `validation_time` allows setting the time point at which all certificates are validated. This is really only useful for testing. The default is the current system clock's current time. `ocsp_timeout` sets the timeout for OCSP requests. The default of 0 disables OCSP checks completely. `ocsp_resp` allows adding additional OCSP responses retrieved from outside of the path validation. Note that OCSP online checks are done only as long as the http_util module was compiled in. Availability of online OCSP checks can be checked using the macro BOTAN_HAS_ONLINE_REVOCATION_CHECKS.

For the different flavors of `x509_path_validate`, check `x509path.h`.

The result of the validation is returned as a class:

class Path_Validation_Result

Specifies the result of the validation

bool **successful_validation**() **const**
Returns true if a certificate path from *end_cert* to a trusted root was found and all path validation checks passed.

std::string **result_string**() **const**
Returns a descriptive string of the validation status (for instance "Verified", "Certificate is not yet valid", or "Signature error"). This is the string value of the *result* function below.

const *X509_Certificate* &**trust_root**() **const**

If the validation was successful, returns the certificate which is acting as the trust root for *end_cert*.

const std::vector<*X509_Certificate*> &**cert_path**() **const**
Returns the full certificate path starting with the end entity certificate and ending in the trust root.

Certificate_Status_Code **result**() **const**
Returns the 'worst' error that occurred during validation. For instance, we do not want an expired certificate with an invalid signature to be reported to the user as being simply expired (a relatively innocuous and common error) when the signature isn't even valid.

const std::vector<std::set<Certificate_Status_Code>> &**all_statuses**() **const**
For each certificate in the chain, returns a set of status which indicate all errors which occurred during validation. This is primarily useful for diagnostic purposes.

std::set<std::string> **trusted_hashes**() **const**
Returns the set of all cryptographic hash functions which are implicitly trusted for this validation to be correct.

A `Path_Validation_Restrictions` is passed to the path validator and specifies restrictions and options for the validation step. The two constructors are:

Path_Validation_Restrictions(bool *require_rev*, size_t *minimum_key_strength*, bool *ocsp_all_intermediates*, **const** std::set<std::string> &*trusted_hashes*)

If *require_rev* is true, then any path without revocation information (CRL or OCSP check) is rejected with the code *NO_REVOCATION_DATA*. The *minimum_key_strength* parameter specifies the minimum strength of public key signature we will accept is. The set of hash names *trusted_hashes* indicates which hash functions we'll accept for cryptographic signatures. Any untrusted hash will cause the error case *UNTRUSTED_HASH*.

Path_Validation_Restrictions(bool *require_rev* = false, size_t *minimum_key_strength* = 80, bool *ocsp_all_intermediates* = false)

A variant of the above with some convenient defaults. The current default *minimum_key_strength* of 80 roughly corresponds to 1024 bit RSA. The set of trusted hashes is set to all SHA-2 variants, and, if *minimum_key_strength* is less than or equal to 80, then SHA-1 signatures will also be accepted.

14.5.2 Creating New Certificates

A CA is represented by the type `X509_CA`, which can be found in `x509_ca.h`. A CA always needs its own certificate, which can either be a self-signed certificate (see below on how to create one) or one issued by another CA (see the section on PKCS #10 requests). Creating a CA object is done by the following constructor:

X509_CA::**X509_CA**(**const** *X509_Certificate* &*cert*, **const** Private_Key &*key*, **const** std::string &*hash_fn*, *RandomNumberGenerator* &*rng*)

The private `key` is the private key corresponding to the public key in the CA's certificate. `hash_fn` is the name of the hash function to use for signing, e.g., *SHA-256*. `rng` is queried for random during signing.

There is an alternative constructor that lets you set additional options, namely the padding scheme that will be used by the X509_CA object to sign certificates and certificate revocation lists. If the padding is not set explicitly, the CA will use the padding scheme that was used when signing the CA certificate.

X509_CA::**X509_CA**(**const** *X509_Certificate* &*cert*, **const** Private_Key &*key*, **const** std::map<std::string, std::string> &*opts*, **const** std::string &*hash_fn*, *RandomNumberGenerator* &*rng*)

The only option valid at this moment is "padding". The supported padding schemes can be found in src/lib/pubkey/padding.cpp. Some alternative names for the padding schemes are understood, as well.

Requests for new certificates are supplied to a CA in the form of PKCS #10 certificate requests (called a `PKCS10_Request` object in Botan). These are decoded in a similar manner to certificates/CRLs/etc. A request is vetted by humans (who somehow verify that the name in the request corresponds to the name of the entity who requested it), and then signed by a CA key, generating a new certificate:

X509_Certificate `X509_CA`::**sign_request**(**const** PKCS10_Request &*req*, *RandomNumberGenerator* &*rng*, **const** X509_Time &*not_before*, **const** X509_Time &*not_after*)

14.6 Generating CRLs

As mentioned previously, the ability to process CRLs is highly important in many PKI systems. In fact, according to strict X.509 rules, you must not validate any certificate if the appropriate CRLs are not available (though hardly any systems are that strict). In any case, a CA should have a valid CRL available at all times.

Of course, you might be wondering what to do if no certificates have been revoked. Never fear; empty CRLs, which revoke nothing at all, can be issued. To generate a new, empty CRL, just call

X509_CRL `X509_CA::new_crl`(*RandomNumberGenerator* &*rng*, uint32_t *next_update* = 0)

This function will return a new, empty CRL. The `next_update` parameter is the number of seconds before the CRL expires. If it is set to the (default) value of zero, then a reasonable default (currently 7 days) will be used.

On the other hand, you may have issued a CRL before. In that case, you will want to issue a new CRL that contains all previously revoked certificates, along with any new ones. This is done by calling

X509_CRL `X509_CA::update_crl`(**const** X509_CRL &*last_crl*, std::vector<CRL_Entry> *new_entries*, *RandomNumberGenerator* &*rng*, size_t *next_update* = 0)

Where `last_crl` is the last CRL this CA issued, and `new_entries` is a list of any newly revoked certificates. The function returns a new `X509_CRL` to make available for clients.

The `CRL_Entry` type is a structure that contains, at a minimum, the serial number of the revoked certificate. As serial numbers are never repeated, the pairing of an issuer and a serial number (should) distinctly identify any certificate. In this case, we represent the serial number as a `secure_vector<uint8_t>` called `serial`. There are two additional (optional) values, an enumeration called `CRL_Code` that specifies the reason for revocation (`reason`), and an object that represents the time that the certificate became invalid (if this information is known).

If you wish to remove an old entry from the CRL, insert a new entry for the same cert, with a `reason` code of `REMOVE_FROM_CRL`. For example, if a revoked certificate has expired 'normally', there is no reason to continue to explicitly revoke it, since clients will reject the cert as expired in any case.

14.7 Self-Signed Certificates

Generating a new self-signed certificate can often be useful, for example when setting up a new root CA, or for use in specialized protocols. The library provides a utility function for this:

X509_Certificate **create_self_signed_cert**(**const** X509_Cert_Options &*opts*, **const** Private_Key &*key*, **const** std::string &*hash_fn*, *RandomNumberGenerator* &*rng*)

Where `key` is the private key you wish to use (the public key, used in the certificate itself is extracted from the private key), and `opts` is an structure that has various bits of information that will be used in creating the certificate (this structure, and its use, is discussed below).

14.8 Creating PKCS #10 Requests

Also in `x509self.h`, there is a function for generating new PKCS #10 certificate requests:

PKCS10_Request **create_cert_req**(**const** X509_Cert_Options &*opts*, **const** Private_Key &*key*, **const** std::string &*hash_fn*, *RandomNumberGenerator* &*rng*)

This function acts quite similarly to *create_self_signed_cert*, except it instead returns a PKCS #10 certificate request. After creating it, one would typically transmit it to a CA, who signs it and returns a freshly minted X.509 certificate.

PKCS10_Request `PKCS10_Request::create`(**const** Private_Key &*key*, **const** *X509_DN* &*subject_dn*, **const** *Extensions* &*extensions*, **const** std::string &*hash_fn*, *RandomNumberGenerator* &*rng*, **const** std::string &*padding_scheme* = "", **const** std::string &*challenge* = "")

This function (added in 2.5) is similar to `create_cert_req` but allows specifying all the parameters directly. In fact `create_cert_req` just creates the DN and extensions from the options, then uses this call to actually create the `PKCS10_Request` object.

14.9 Certificate Options

What is this `X509_Cert_Options` thing we've been passing around? It's a class representing a bunch of information that will end up being stored into the certificate. This information comes in 3 major flavors: information about the subject (CA or end-user), the validity period of the certificate, and restrictions on the usage of the certificate. For special cases, you can also add custom X.509v3 extensions.

First and foremost is a number of `std::string` members, which contains various bits of information about the user: `common_name`, `serial_number`, `country`, `organization`, `org_unit`, `locality`, `state`, `email`, `dns_name`, and `uri`. As many of these as possible should be filled it (especially an email address), though the only required ones are `common_name` and `country`.

There is another value that is only useful when creating a PKCS #10 request, which is called `challenge`. This is a challenge password, which you can later use to request certificate revocation (*if* the CA supports doing revocations in this manner).

Then there is the validity period; these are set with `not_before` and `not_after`. Both of these functions also take a `std::string`, which specifies when the certificate should start being valid, and when it should stop being valid. If you don't set the starting validity period, it will automatically choose the current time. If you don't set the ending time, it will choose the starting time plus a default time period. The arguments to these functions specify the time in the following format: "2002/11/27 1:50:14". The time is in 24-hour format, and the date is encoded as year/month/day. The date must be specified, but you can omit the time or trailing parts of it, for example "2002/11/27 1:50" or "2002/11/27".

Third, you can set constraints on a key. The one you're mostly likely to want to use is to create (or request) a CA certificate, which can be done by calling the member function `CA_key`. This should only be used when needed.

Moreover, you can specify the padding scheme to be used when digital signatures are computed by calling function `set_padding_scheme` with a string representing the padding scheme. This way, you can control the padding scheme for self-signed certificates and PKCS #10 requests. The padding scheme used by a CA when building a certificate or a certificate revocation list can be set in the `X509_CA` constructor. The supported padding schemes can be found in src/lib/pubkey/padding.cpp. Some alternative names for the padding schemes are understood, as well.

Other constraints can be set by calling the member functions `add_constraints` and `add_ex_constraints`. The first takes a `Key_Constraints` value, and replaces any previously set value. If no value is set, then the certificate key is marked as being valid for any usage. You can set it to any of the following (for more than one usage, OR them together): `DIGITAL_SIGNATURE`, `NON_REPUDIATION`, `KEY_ENCIPHERMENT`, `DATA_ENCIPHERMENT`, `KEY_AGREEMENT`, `KEY_CERT_SIGN`, `CRL_SIGN`, `ENCIPHER_ONLY`, `DECIPHER_ONLY`. Many of these have quite special semantics, so you should either consult the appropriate standards document (such as RFC 5280), or just not call `add_constraints`, in which case the appropriate values will be chosen for you.

The second function, `add_ex_constraints`, allows you to specify an OID that has some meaning with regards to restricting the key to particular usages. You can, if you wish, specify any OID you like, but there is a set of standard ones that other applications will be able to understand. These are the ones specified by the PKIX standard, and are named "PKIX.ServerAuth" (for TLS server authentication), "PKIX.ClientAuth" (for TLS client authentication), "PKIX.CodeSigning", "PKIX.EmailProtection" (most likely for use with S/MIME), "PKIX.IPsecUser", "PKIX.IPsecTunnel", "PKIX.IPsecEndSystem", and "PKIX.TimeStamping". You can call "add_ex_constraints" any number of times - each new OID will be added to the list to include in the certificate.

Lastly, you can add any X.509v3 extensions in the *extensions* member, which is useful if you want to encode a custom extension, or encode an extension in a way differently from how Botan defaults.

14.9.1 OCSP Requests

A client makes an OCSP request to what is termed an 'OCSP responder'. This responder returns a signed response attesting that the certificate in question has not been revoked. The most recent OCSP specification is as of this writing

RFC 6960 (https://tools.ietf.org/html/rfc6960.html).

Normally OCSP validation happens automatically as part of X.509 certificate validation, as long as OCSP is enabled (by setting a non-zero `ocsp_timeout` in the call to `x509_path_validate`, or for TLS by implementing the related `tls_verify_cert_chain_ocsp_timeout` callback and returning a non-zero value from that). So most applications should not need to directly manipulate OCSP request and response objects.

For those that do, the primary ocsp interface is in `ocsp.h`. First a request must be formed, using information contained in the subject certificate and in the subject's issuing certificate.

class `OCSP::Request`

`OCSP::Request`(**const** *X509_Certificate* &*issuer_cert*, **const** *BigInt* &*subject_serial*)
Create a new OCSP request

`OCSP::Request`(**const** *X509_Certificate* &*issuer_cert*, **const** *X509_Certificate* &*subject_cert*)
Variant of the above, using serial number from `subject_cert`.

std::vector<uint8_t> **BER_encode**() **const**
Encode the current OCSP request as a binary string.

std::string **base64_encode**() **const**
Encode the current OCSP request as a base64 string.

Then the response is parsed and validated, and if valid, can be consulted for certificate status information.

class `OCSP::Response`

`OCSP::Response`(**const** uint8_t *response_bits*[], size_t *response_bits_len*)
Attempts to parse `response_bits` as an OCSP response. Throws an exception if parsing fails. Note that this does not verify that the OCSP response is valid (ie that the signature is correct), merely that the ASN.1 structure matches an OCSP response.

Certificate_Status_Code **check_signature**(**const** std::vector<Certificate_Store *> &*trust_roots*, **const** std::vector<std::shared_ptr<**const** *X509_Certificate*>> &*cert_path* = **const** std::vector<std::shared<**const** *X509_Certificate*>>()) **const**
Find the issuing certificate of the OCSP response, and check the signature.

If possible, pass the full certificate path being validated in the optional `cert_path` argument: this additional information helps locate the OCSP signer's certificate in some cases. If this does not return `Certificate_Status_Code::OCSP_SIGNATURE_OK`, then the request must not be be used further.

Certificate_Status_Code **verify_signature**(**const** *X509_Certificate* &*issuing_cert*) **const**
If the certificate that issued the OCSP response is already known (eg, because in some specific application all the OCSP responses will always be signed by a single trusted issuer whose cert is baked into the code) this provides an alternate version of *check_signature*.

Certificate_Status_Code **status_for**(**const** *X509_Certificate* &*issuer*, **const** *X509_Certificate* &*subject*, std::chrono::system_clock::time_point *ref_time* = std::chrono::system_clock::now()) **const**
Assuming the signature is valid, returns the status for the subject certificate. Make sure to get the ordering of the issuer and subject certificates correct.

The `ref_time` is normally just the system clock, but can be used if validation against some other reference time is desired (such as for testing, to verify an old previously valid OCSP response, or to use an alternate time source such as the Roughtime protocol instead of the local client system clock).

const X509_Time &**produced_at**() **const**
Return the time this OCSP response was (claimed to be) produced at.

const *X509_DN* &**signer_name**() **const**
Return the distinguished name of the signer. This is used to help find the issuing certificate.

This field is optional in OCSP responses, and may not be set.

const std::vector<uint8_t> &**signer_key_hash**() **const**
Return the SHA-1 hash of the public key of the signer. This is used to help find the issuing certificate. The `Certificate_Store` API `find_cert_by_pubkey_sha1` can search on this value.

This field is optional in OCSP responses, and may not be set.

const std::vector<uint8_t> &**raw_bits**() **const**
Return the entire raw ASN.1 blob (for debugging or specialized decoding needs)

One common way of making OCSP requests is via HTTP, see **RFC 2560** (https://tools.ietf.org/html/rfc2560.html) Appendix A for details. A basic implementation of this is the function `online_check`, which is available as long as the `http_util` module was compiled in; check by testing for the macro `BOTAN_HAS_HTTP_UTIL`.

OCSP::*Response* **online_check**(**const** *X509_Certificate* &*issuer*, **const** *BigInt* &*subject_serial*, **const** std::string &*ocsp_responder*, **const** Certificate_Store **trusted_roots*)
Assemble a OCSP request for serial number `subject_serial` and attempt to request it to responder at URI `ocsp_responder` over a new HTTP socket, parses and returns the response. If trusted_roots is not null, then the response is additionally validated using OCSP response API `check_signature`. Otherwise, this call must be performed later by the application.

OCSP::*Response* **online_check**(**const** *X509_Certificate* &*issuer*, **const** *X509_Certificate* &*subject*, **const** Certificate_Store **trusted_roots*)
Variant of the above but uses serial number and OCSP responder URI from `subject`.

CHAPTER

FIFTEEN

TRANSPORT LAYER SECURITY (TLS)

New in version 1.11.0.

Botan has client and server implementations of various versions of the TLS protocol, including TLS v1.0, TLS v1.1, and TLS v1.2. As of version 1.11.13, support for the insecure SSLv3 protocol has been removed.

There is also support for DTLS (v1.0 and v1.2), a variant of TLS adapted for operation on datagram transports such as UDP and SCTP. DTLS support should be considered as beta quality and further testing is invited.

The TLS implementation does not know anything about sockets or the network layer. Instead, it calls a user provided callback (hereafter `output_fn`) whenever it has data that it would want to send to the other party (for instance, by writing it to a network socket), and whenever the application receives some data from the counterparty (for instance, by reading from a network socket) it passes that information to TLS using *`TLS::Channel::received_data`*. If the data passed in results in some change in the state, such as a handshake completing, or some data or an alert being received from the other side, then the appropriate user provided callback will be invoked.

If the reader is familiar with OpenSSL's BIO layer, it might be analogous to saying the only way of interacting with Botan's TLS is via a *BIO_mem* I/O abstraction. This makes the library completely agnostic to how you write your network layer, be it blocking sockets, libevent, asio, a message queue, lwIP on RTOS, some carrier pidgeons, etc.

Starting in 1.11.31, the application callbacks are encapsulated as the class `TLS::Callbacks` with the following members. The first four (`tls_emit_data`, `tls_record_received`, `tls_alert`, and `tls_session_established`) are mandatory for using TLS, all others are optional and provide additional information about the connection.

void **`tls_emit_data`**(**`const`** uint8_t *data*[], size_t *data_len*)
: Mandatory. The TLS stack requests that all bytes of *data* be queued up to send to the counterparty. After this function returns, the buffer containing *data* will be overwritten, so a copy of the input must be made if the callback cannot send the data immediately.

  As an example you could `send` to perform a blocking write on a socket, or append the data to a queue managed by your application, and initiate an asynchronous write.

  For TLS all writes must occur *in the order requested*. For DTLS this ordering is not strictly required, but is still recommended.

void **`tls_record_received`**(uint64_t *rec_no*, **`const`** uint8_t *data*[], size_t *data_len*)
: Mandatory. Called once for each application_data record which is received, with the matching (TLS level) record sequence number.

  Currently empty records are ignored and do not instigate a callback, but this may change in a future release.

  As with `tls_emit_data`, the array will be overwritten sometime after the callback returns, so a copy should be made if needed.

  For TLS the record number will always increase.

For DTLS, it is possible to receive records with the *rec_no* field out of order, or with gaps, corresponding to reordered or lost datagrams.

void **tls_alert**(Alert *alert*)
Mandatory. Called when an alert is received from the peer. Note that alerts received before the handshake is complete are not authenticated and could have been inserted by a MITM attacker.

bool **tls_session_established**(**const** TLS::*Session* &*session*)
Mandatory. Called whenever a negotiation completes. This can happen more than once on any connection, if renegotiation occurs. The *session* parameter provides information about the session which was just established.

If this function returns false, the session will not be cached for later resumption.

If this function wishes to cancel the handshake, it can throw an exception which will send a close message to the counterparty and reset the connection state.

std::string **tls_server_choose_app_protocol**(**const** std::vector<std::string> &*client_protos*)
Optional. Called by the server when a client includes a list of protocols in the ALPN extension. The server then choose which protocol to use, or "" to disable sending any ALPN response. The default implementation returns the empty string all of the time, effectively disabling ALPN responses.

void **tls_inspect_handshake_msg**(**const** Handshake_Message&)
This callback is optional, and can be used to inspect all handshake messages while the session establishment occurs.

void **tls_modify_extensions**(*Extensions* &*extn*, Connection_Side *which_side*)
This callback is optional, and can be used to modify extensions before they are sent to the peer. For example this enables adding a custom extension, or replacing or removing an extension set by the library.

void **tls_examine_extensions**(**const** *Extensions* &*extn*, Connection_Side *which_side*)
This callback is optional, and can be used to examine extensions sent by the peer.

void **tls_log_error**(**const** char **msg*)
Optional logging for an error message. (Not currently used)

void **tls_log_debug**(**const** char **msg*)
Optional logging for an debug message. (Not currently used)

void **tls_log_debug_bin**(**const** char **descr*, **const** uint8_t *val*[], size_t *len*)
Optional logging for an debug value. (Not currently used)

std::string **tls_decode_group_param**(TLS::Group_Params *group_param*)
Optional. Called by the server when a client hello includes a list of supported groups in the supported_groups extension and by the client when decoding the server key exchange including the selected curve identifier. The function should return the name of the DH group or elliptic curve the passed TLS group identifier should be mapped to. Therefore this callback enables the use of custom elliptic curves or DH groups in TLS, if both client and server map the custom identifiers correctly. Please note that it is required to allow the group TLS identifier in in the used *TLS::Policy*.

Versions from 1.11.0 to 1.11.30 did not have `TLS::Callbacks` and instead used independent std::functions to pass the various callback functions. This interface is currently still included but is deprecated and will be removed in a future release. For the documentation for this interface, please check the docs for 1.11.30. This version of the manual only documents the new interface added in 1.11.31.

15.1 TLS Channels

TLS servers and clients share an interface called *TLS::Channel*. A TLS channel (either client or server object) has these methods available:

class TLS::**Channel**

size_t **received_data**(**const** uint8_t *buf*[], size_t *buf_size*)

size_t **received_data**(**const** std::vector<uint8_t> &*buf*)
This function is used to provide data sent by the counterparty (eg data that you read off the socket layer). Depending on the current protocol state and the amount of data provided this may result in one or more callback functions that were provided to the constructor being called.

The return value of `received_data` specifies how many more bytes of input are needed to make any progress, unless the end of the data fell exactly on a message boundary, in which case it will return 0 instead.

void **send**(**const** uint8_t *buf*[], size_t *buf_size*)

void **send**(**const** std::string &*str*)

void **send**(**const** std::vector<uint8_t> &*vec*)
Create one or more new TLS application records containing the provided data and send them. This will eventually result in at least one call to the `output_fn` callback before `send` returns.

If the current TLS connection state is unable to transmit new application records (for example because a handshake has not yet completed or the connection has already ended due to an error) an exception will be thrown.

void **close**()
A close notification is sent to the counterparty, and the internal state is cleared.

void **send_alert**(**const** *Alert* &*alert*)
Some other alert is sent to the counterparty. If the alert is fatal, the internal state is cleared.

bool **is_active**()
Returns true if and only if a handshake has been completed on this connection and the connection has not been subsequently closed.

bool **is_closed**()
Returns true if and only if either a close notification or a fatal alert message have been either sent or received.

bool **timeout_check**()
This function does nothing unless the channel represents a DTLS connection and a handshake is actively in progress. In this case it will check the current timeout state and potentially initiate retransmission of handshake packets. Returns true if a timeout condition occurred.

void **renegotiate**(bool *force_full_renegotiation* = false)
Initiates a renegotiation. The counterparty is allowed by the protocol to ignore this request. If a successful renegotiation occurs, the *handshake_cb* callback will be called again.

If *force_full_renegotiation* is false, then the client will attempt to simply renew the current session - this will refresh the symmetric keys but will not change the session master secret. Otherwise it will initiate a completely new session.

For a server, if *force_full_renegotiation* is false, then a session resumption will be allowed if the client attempts it. Otherwise the server will prevent resumption and force the creation of a new session.

std::vector<*X509_Certificate*> **peer_cert_chain**()

Returns the certificate chain of the counterparty. When acting as a client, this value will be non-empty unless the client's policy allowed anonymous connections and the server then chose an anonymous ciphersuite. Acting as a server, this value will ordinarily be empty, unless the server requested a certificate and the client responded with one.

SymmetricKey **key_material_export**(**const** std::string &*label*, **const** std::string &*context*, size_t *length*)

Returns an exported key of *length* bytes derived from *label*, *context*, and the session's master secret and client and server random values. This key will be unique to this connection, and as long as the session master secret remains secure an attacker should not be able to guess the key.

Per **RFC 5705** (https://tools.ietf.org/html/rfc5705.html), *label* should begin with "EXPERIMENTAL" unless the label has been standardized in an RFC.

15.2 TLS Clients

class TLS::**Client**

Client(Callbacks &*callbacks*, Session_Manager &*session_manager*, *Credentials_Manager* &*creds*, **const** *Policy* &*policy*, *RandomNumberGenerator* &*rng*, **const** Server_Information &*server_info* = Server_Information(), **const** *Protocol_Version offer_version* = *Protocol_Version*::*latest_tls_version*(), **const** std::vector<std::string> &*next_protocols* = std::vector<std::string>(), size_t *reserved_io_buffer_size* = 16 * 1024)

Initialize a new TLS client. The constructor will immediately initiate a new session.

The *callbacks* parameter specifies the various application callbacks which pertain to this particular client connection.

The *session_manager* is an interface for storing TLS sessions, which allows for session resumption upon reconnecting to a server. In the absence of a need for persistent sessions, use `TLS::Session_Manager_In_Memory` which caches connections for the lifetime of a single process. See *TLS Session Managers* for more about session managers.

The *credentials_manager* is an interface that will be called to retrieve any certificates, secret keys, pre-shared keys, or SRP information; see *Credentials Manager* for more information.

Use the optional *server_info* to specify the DNS name of the server you are attempting to connect to, if you know it. This helps the server select what certificate to use and helps the client validate the connection.

Note that the server name indicator name must be a FQDN. IP addresses are not allowed by RFC 6066 and may lead to interoperability problems.

Use the optional *offer_version* to control the version of TLS you wish the client to offer. Normally, you'll want to offer the most recent version of (D)TLS that is available, however some broken servers are intolerant of certain versions being offered, and for classes of applications that have to deal with such servers (typically web browsers) it may be necessary to implement a version backdown strategy if the initial attempt fails.

> **Warning:** Implementing such a backdown strategy allows an attacker to downgrade your connection to the weakest protocol that both you and the server support.

Setting *offer_version* is also used to offer DTLS instead of TLS; use *TLS::Protocol_Version::latest_dtls_version*.

Optionally, the client will advertise *app_protocols* to the server using the ALPN extension.

The optional *reserved_io_buffer_size* specifies how many bytes to pre-allocate in the I/O buffers. Use this if you want to control how much memory the channel uses initially (the buffers will be resized as needed to process inputs). Otherwise some reasonable default is used.

15.2.1 Code Example

A minimal example of a TLS client is provided below. The full code for a TLS client using BSD sockets is in *src/cli/tls_client.cpp*

```
#include <botan/tls_client.h>
#include <botan/tls_callbacks.h>
#include <botan/tls_session_manager.h>
#include <botan/tls_policy.h>
#include <botan/auto_rng.h>
#include <botan/certstor.h>

/**
 * @brief Callbacks invoked by TLS::Channel.
 *
 * Botan::TLS::Callbacks is an abstract class.
 * For improved readability, only the functions that are mandatory
 * to implement are listed here. See src/lib/tls/tls_callbacks.h.
 */
class Callbacks : public Botan::TLS::Callbacks
{
   public:
      void tls_emit_data(const uint8_t data[], size_t size) override
         {
         // send data to tls server, e.g., using BSD sockets or boost asio
         }

      void tls_record_received(uint64_t seq_no, const uint8_t data[], size_t size)␣
↪override
         {
         // process full TLS record received by tls server, e.g.,
         // by passing it to the application
         }

      void tls_alert(Botan::TLS::Alert alert) override
         {
         // handle a tls alert received from the tls server
         }

      bool tls_session_established(const Botan::TLS::Session& session) override
         {
         // the session with the tls server was established
         // return false to prevent the session from being cached, true to
         // cache the session in the configured session manager
         return false;
         }
};

      // send data to the tls server using client.send_data()
      }
   }
```

15.3 TLS Servers

class TLS::**Server**

Server(Callbacks &*callbacks*, Session_Manager &*session_manager*, *Credentials_Manager* &*creds*, **const** *Policy* &*policy*, *RandomNumberGenerator* &*rng*, bool *is_datagram* = false, size_t *reserved_io_buffer_size* = 16 * 1024)

The first 5 arguments as well as the final argument *reserved_io_buffer_size*, are treated similarly to the *client*.

If a client sends the ALPN extension, the `callbacks` function `tls_server_choose_app_protocol` will be called and the result sent back to the client. If the empty string is returned, the server will not send an ALPN response. The function can also throw an exception to abort the handshake entirely, the ALPN specification says that if this occurs the alert should be of type *NO_APPLICATION_PROTOCOL*.

The optional argument *is_datagram* specifies if this is a TLS or DTLS server; unlike clients, which know what type of protocol (TLS vs DTLS) they are negotiating from the start via the *offer_version*, servers would not until they actually received a client hello.

15.3.1 Code Example

A minimal example of a TLS server is provided below. The full code for a TLS server using asio is in *src/cli/tls_proxy.cpp*.

```
#include <botan/tls_client.h>
#include <botan/tls_callbacks.h>
#include <botan/tls_session_manager.h>
#include <botan/tls_policy.h>
#include <botan/auto_rng.h>
#include <botan/certstor.h>
#include <botan/pk_keys.h>

#include <memory>

/**
 * @brief Callbacks invoked by TLS::Channel.
 *
 * Botan::TLS::Callbacks is an abstract class.
 * For improved readability, only the functions that are mandatory
 * to implement are listed here. See src/lib/tls/tls_callbacks.h.
 */
class Callbacks : public Botan::TLS::Callbacks
{
   public:
      void tls_emit_data(const uint8_t data[], size_t size) override
         {
         // send data to tls client, e.g., using BSD sockets or boost asio
```

(continues on next page)

(continued from previous page)

```
         }

      void tls_record_received(uint64_t seq_no, const uint8_t data[], size_t size)␣
↪override
         {
         // process full TLS record received by tls client, e.g.,
         // by passing it to the application
         }

      void tls_alert(Botan::TLS::Alert alert) override
         {
         // handle a tls alert received from the tls server
         }

      bool tls_session_established(const Botan::TLS::Session& session) override
         {
         // the session with the tls client was established
         // return false to prevent the session from being cached, true to
         // cache the session in the configured session manager
         return false;
         }
};

/**
 * @brief Credentials storage for the tls server.
 *
 * It returns a certificate and the associated private key to
 * authenticate the tls server to the client.
 * TLS client authentication is not requested.
 * See src/lib/tls/credentials_manager.h.
 */
class Server_Credentials : public Botan::Credentials_Manager
{
   public:
      Server_Credentials() : m_key(Botan::PKCS8::load_key("botan.randombit.net.key"))
         {
         }

      std::vector<Botan::Certificate_Store*> trusted_certificate_authorities(
         const std::string& type,
         const std::string& context) override
         {
         // if client authentication is required, this function
         // shall return a list of certificates of CAs we trust
         // for tls client certificates, otherwise return an empty list
         return std::vector<Certificate_Store*>();
         }

      std::vector<Botan::X509_Certificate> cert_chain(
         const std::vector<std::string>& cert_key_types,
         const std::string& type,
         const std::string& context) override
         {
         // return the certificate chain being sent to the tls client
         // e.g., the certificate file "botan.randombit.net.crt"
         return { Botan::X509_Certificate("botan.randombit.net.crt") };
         }
```

(continues on next page)

(continued from previous page)

```
      Botan::Private_Key* private_key_for(const Botan::X509_Certificate& cert,
         const std::string& type,
         const std::string& context) override
         {
         // return the private key associated with the leaf certificate,
         // in this case the one associated with "botan.randombit.net.crt"
         return &m_key;
         }

      private:
         std::unique_ptr<Botan::Private_Key> m_key;
};

int main()
   {
   // prepare all the parameters
   Callbacks callbacks;
   Botan::AutoSeeded_RNG rng;
   Botan::TLS::Session_Manager_In_Memory session_mgr(rng);
   Botan::Client_Credentials creds;
   Botan::TLS::Strict_Policy policy;

   // accept tls connection from client
   Botan::TLS::Server server(callbacks,
                             session_mgr,
                             creds,
                             policy,
                             rng);

   // read data received from the tls client, e.g., using BSD sockets or boost asio
   // and pass it to server.received_data().
   // ...

   // send data to the tls client using server.send_data()
   // ...
   }
```

15.4 TLS Sessions

TLS allows clients and servers to support *session resumption*, where the end point retains some information about an established session and then reuse that information to bootstrap a new session in way that is much cheaper computationally than a full handshake.

Every time your handshake callback is called, a new session has been established, and a `TLS::Session` is included that provides information about that session:

class TLS::**Session**

Protocol_Version **version**() **const**
: Returns the *protocol version* that was negotiated

Ciphersuite **ciphersite**() **const**
: Returns the *ciphersuite* that was negotiated.

Server_Information **server_info**() **const**
: Returns information that identifies the server side of the connection. This is useful for the client in that it identifies what was originally passed to the constructor. For the server, it includes the name the client specified in the server name indicator extension.

std::vector<*X509_Certificate*> **peer_certs**() **const**
: Returns the certificate chain of the peer

std::string **srp_identifier**() **const**
: If an SRP ciphersuite was used, then this is the identifier that was used for authentication.

bool **secure_renegotiation**() **const**
: Returns `true` if the connection was negotiated with the correct extensions to prevent the renegotiation attack.

std::vector<uint8_t> **encrypt**(**const** SymmetricKey &*key*, *RandomNumberGenerator* &*rng*)
: Encrypts a session using a symmetric key *key* and returns a raw binary value that can later be passed to `decrypt`. The key may be of any length.

  Currently the implementation encrypts the session using AES-256 in GCM mode with a random nonce.

static *Session* **decrypt**(**const** uint8_t *ciphertext*[], size_t *length*, **const** SymmetricKey &*key*)
: Decrypts a session that was encrypted previously with `encrypt` and `key`, or throws an exception if decryption fails.

secure_vector<uint8_t> **DER_encode**() **const**
: Returns a serialized version of the session.

> **Warning:** The return value of `DER_encode` contains the master secret for the session, and an attacker who recovers it could recover plaintext of previous sessions or impersonate one side to the other.

15.5 TLS Session Managers

You may want sessions stored in a specific format or storage type. To do so, implement the `TLS::Session_Manager` interface and pass your implementation to the `TLS::Client` or `TLS::Server` constructor.

class `TLS::`**Session_Mananger**

void **save**(**const** *Session* &*session*)
: Save a new *session*. It is possible that this sessions session ID will replicate a session ID already stored, in which case the new session information should overwrite the previous information.

void **remove_entry**(**const** std::vector<uint8_t> &*session_id*)
: Remove the session identified by *session_id*. Future attempts at resumption should fail for this session.

bool **load_from_session_id**(**const** std::vector<uint8_t> &*session_id*, *Session* &*session*)
: Attempt to resume a session identified by *session_id*. If located, *session* is set to the session data previously passed to *save*, and `true` is returned. Otherwise *session* is not modified and `false` is returned.

bool **load_from_server_info**(**const** Server_Information &*server*, *Session* &*session*)
: Attempt to resume a session with a known server.

std::chrono::seconds **session_lifetime**() **const**
Returns the expected maximum lifetime of a session when using this session manager. Will return 0 if the lifetime is unknown or has no explicit expiration policy.

15.5.1 In Memory Session Manager

The `TLS::Session_Manager_In_Memory` implementation saves sessions in memory, with an upper bound on the maximum number of sessions and the lifetime of a session.

It is safe to share a single object across many threads as it uses a lock internally.

class TLS::**Session_Managers_In_Memory**

Session_Manager_In_Memory(*RandomNumberGenerator* &*rng*, size_t *max_sessions* = 1000, std::chrono::seconds *session_lifetime* = 7200)
Limits the maximum number of saved sessions to *max_sessions*, and expires all sessions older than *session_lifetime*.

15.5.2 Noop Session Mananger

The `TLS::Session_Manager_Noop` implementation does not save sessions at all, and thus session resumption always fails. Its constructor has no arguments.

15.5.3 SQLite3 Session Manager

This session manager is only available if support for SQLite3 was enabled at build time. If the macro `BOTAN_HAS_TLS_SQLITE3_SESSION_MANAGER` is defined, then `botan/tls_session_manager_sqlite.h` contains `TLS::Session_Manager_SQLite` which stores sessions persistently to a sqlite3 database. The session data is encrypted using a passphrase, and stored in two tables, named `tls_sessions` (which holds the actual session information) and `tls_sessions_metadata` (which holds the PBKDF information).

> **Warning:** The hostnames associated with the saved sessions are stored in the database in plaintext. This may be a serious privacy risk in some applications.

class TLS::**Session_Manager_SQLite**

Session_Manager_SQLite(**const** std::string &*passphrase*, *RandomNumberGenerator* &*rng*, **const** std::string &*db_filename*, size_t *max_sessions* = 1000, std::chrono::seconds *session_lifetime* = 7200)
Uses the sqlite3 database named by *db_filename*.

15.6 TLS Policies

`TLS::Policy` is how an application can control details of what will be negotiated during a handshake. The base class acts as the default policy. There is also a `Strict_Policy` (which forces only secure options, reducing compatibility) and `Text_Policy` which reads policy settings from a file.

class TLS::**Policy**

std::vector<std::string> **allowed_ciphers**() **const**

Returns the list of ciphers we are willing to negotiate, in order of preference.

Clients send a list of ciphersuites in order of preference, servers are free to choose any of them. Some servers will use the clients preferences, others choose from the clients list prioritizing based on its preferences.

No export key exchange mechanisms or ciphersuites are supported by botan. The null encryption ciphersuites (which provide only authentication, sending data in cleartext) are also not supported by the implementation and cannot be negotiated.

Cipher names without an explicit mode refers to CBC+HMAC ciphersuites.

Default value: "ChaCha20Poly1305", "AES-256/GCM", "AES-128/GCM"

Also allowed: "AES-256", "AES-128", "AES-256/CCM", "AES-128/CCM", "AES-256/CCM(8)", "AES-128/CCM(8)", "Camellia-256/GCM", "Camellia-128/GCM", "ARIA-256/GCM", "ARIA-128/GCM", "Camellia-256", "Camellia-128"

Also allowed (though currently experimental): "AES-128/OCB(12)", "AES-256/OCB(12)"

In versions up to 2.8.0, the CBC and CCM ciphersuites "AES-256", "AES-128", "AES-256/CCM" and "AES-128/CCM" were enabled by default.

Also allowed (although **not recommended**): "SEED", "3DES"

Note: Before 1.11.30 only the non-standard ChaCha20Poly1305 ciphersuite was implemented. The RFC 7905 ciphersuites are supported in 1.11.30 onwards.

Note: Support for the broken RC4 cipher was removed in 1.11.17

Note: SEED and 3DES are deprecated and will be removed in a future release.

---

std::vector<std::string> **allowed_macs**() **const**

Returns the list of algorithms we are willing to use for message authentication, in order of preference.

Default: "AEAD", "SHA-256", "SHA-384", "SHA-1"

A plain hash function indicates HMAC

Note: SHA-256 is preferred over SHA-384 in CBC mode because the protections against the Lucky13 attack are somewhat more effective for SHA-256 than SHA-384.

---

std::vector<std::string> **allowed_key_exchange_methods**() **const**

Returns the list of key exchange methods we are willing to use, in order of preference.

Default: "CECPQ1", "ECDH", "DH"

Note: CECPQ1 key exchange provides post-quantum security to the key exchange by combining NewHope with a standard x25519 ECDH exchange. This prevents an attacker, even one with a quantum computer, from later decrypting the contents of a recorded TLS transcript. The NewHope

algorithm is very fast, but adds roughly 4 KiB of additional data transfer to every TLS handshake. And even if NewHope ends up completely broken, the 'extra' x25519 exchange secures the handshake.

For applications where the additional data transfer size is unacceptable, simply allow only ECDH key exchange in the application policy. DH exchange also often involves transferring several additional Kb (without the benefit of post quantum security) so if CECPQ1 is being disabled for traffic overhead reasons, DH should also be avoid.

Also allowed: "RSA", "SRP_SHA", "ECDHE_PSK", "DHE_PSK", "PSK"

Note: Static RSA ciphersuites are disabled by default since 1.11.34. In addition to not providing forward security, any server which is willing to negotiate these ciphersuites exposes themselves to a variety of chosen ciphertext oracle attacks which are all easily avoided by signing (as in PFS) instead of decrypting.

Note: In order to enable RSA, SRP, or PSK ciphersuites one must also enable authentication method "IMPLICIT", see *allowed_signature_methods*.

---

std::vector<std::string> **allowed_signature_hashes**() **const**
Returns the list of hash algorithms we are willing to use for public key signatures, in order of preference.

Default: "SHA-512", "SHA-384", "SHA-256"

Also allowed (although **not recommended**): "SHA-1"

Note: This is only used with TLS v1.2. In earlier versions of the protocol, signatures are fixed to using only SHA-1 (for DSA/ECDSA) or a MD5/SHA-1 pair (for RSA).

---

std::vector<std::string> **allowed_signature_methods**() **const**
Default: "ECDSA", "RSA"

Also allowed (disabled by default): "DSA", "IMPLICIT", "ANONYMOUS"

"IMPLICIT" enables ciphersuites which are authenticated not by a signature but through a side-effect of the key exchange. In particular this setting is required to enable PSK, SRP, and static RSA ciphersuites.

"ANONYMOUS" allows purely anonymous DH/ECDH key exchanges. **Enabling this is not recommended**

Note: Both DSA authentication and anonymous DH ciphersuites are deprecated, and will be removed in a future release.

---

std::vector<Group_Params> **key_exchange_groups**() **const**
Return a list of ECC curve and DH group TLS identifiers we are willing to use, in order of preference. The default ordering puts the best performing ECC first.

Default: Group_Params::X25519, Group_Params::SECP256R1, Group_Params::BRAINPOOL256R1, Group_Params::SECP384R1, Group_Params::BRAINPOOL384R1, Group_Params::SECP521R1, Group_Params::BRAINPOOL512R1, Group_Params::FFDHE_2048, Group_Params::FFDHE_3072, Group_Params::FFDHE_4096, Group_Params::FFDHE_6144, Group_Params::FFDHE_8192

No other values are currently defined.

bool **use_ecc_point_compression**() **const**
Prefer ECC point compression.

Signals that we prefer ECC points to be compressed when transmitted to us. The other party may not support ECC point compression and therefore may still send points uncompressed.

Note that the certificate used during authentication must also follow the other party's preference.

Default: false

bool **acceptable_protocol_version**(Protocol_Version *version*)
Return true if this version of the protocol is one that we are willing to negotiate.

Default: Accepts TLS v1.0 or higher and DTLS v1.2 or higher.

bool **server_uses_own_ciphersuite_preferences**() **const**
If this returns true, a server will pick the cipher it prefers the most out of the client's list. Otherwise, it will negotiate the first cipher in the client's ciphersuite list that it supports.

bool **negotiate_heartbeat_support**() **const**
If this function returns true, clients will offer the heartbeat support extension, and servers will respond to clients offering the extension. Otherwise, clients will not offer heartbeat support and servers will ignore clients offering heartbeat support.

If this returns true, callers should expect to handle heartbeat data in their `alert_cb`.

Default: false

bool **allow_client_initiated_renegotiation**() **const**
If this function returns true, a server will accept a client-initiated renegotiation attempt. Otherwise it will send the client a non-fatal `no_renegotiation` alert.

Default: true

bool **allow_server_initiated_renegotiation**() **const**
If this function returns true, a client will accept a server-initiated renegotiation attempt. Otherwise it will send the server a non-fatal `no_renegotiation` alert.

Default: false

bool **allow_insecure_renegotiation**() **const**
If this function returns true, we will allow renegotiation attempts even if the counterparty does not support the RFC 5746 extensions.

> **Warning:** Returning true here could expose you to attacks

Default: false

size_t **minimum_signature_strength**() **const**
Return the minimum strength (as `n`, representing `2**n` work) we will accept for a signature algorithm on any certificate.

Use 80 to enable RSA-1024 (*not recommended*), or 128 to require either ECC or large (~3000 bit) RSA keys.

Default: 110 (allowing 2048 bit RSA)

bool **require_cert_revocation_info**() **const**
If this function returns true, and a ciphersuite using certificates was negotiated, then we must have access to a valid CRL or OCSP response in order to trust the certificate.

> **Warning:** Returning false here could expose you to attacks

Default: true

Group_Params **default_dh_group**() **const**
For ephemeral Diffie-Hellman key exchange, the server sends a group parameter. Return the 2 Byte TLS group identifier specifying the group parameter a server should use.

Default: 2048 bit IETF IPsec group ("modp/ietf/2048")

size_t **minimum_dh_group_size**() **const**
Return the minimum size in bits for a Diffie-Hellman group that a client will accept. Due to the design of the protocol the client has only two options - accept the group, or reject it with a fatal alert then attempt to reconnect after disabling ephemeral Diffie-Hellman.

Default: 2048 bits

bool **allow_tls10**() **const**
Return true from here to allow TLS v1.0. Since 2.8.0, returns `false` by default.

bool **allow_tls11**() **const**
Return true from here to allow TLS v1.1. Since 2.8.0, returns `false` by default.

bool **allow_tls12**() **const**
Return true from here to allow TLS v1.2. Returns `true` by default.

size_t **minimum_rsa_bits**() **const**
Minimum accepted RSA key size. Default 2048 bits.

size_t **minimum_dsa_group_size**() **const**
Minimum accepted DSA key size. Default 2048 bits.

size_t **minimum_ecdsa_group_size**() **const**
Minimum size for ECDSA keys (256 bits).

size_t **minimum_ecdh_group_size**() **const**
Minimum size for ECDH keys (255 bits).

void **check_peer_key_acceptable**(**const** Public_Key &*public_key*) **const**

Allows the policy to examine peer public keys. Throw an exception if the key should be rejected. Default implementation checks against policy values *minimum_dh_group_size*, *minimum_rsa_bits*, *minimum_ecdsa_group_size*, and *minimum_ecdh_group_size*.

bool **hide_unknown_users**() **const**
The SRP and PSK suites work using an identifier along with a shared secret. If this function returns true, when an identifier that the server does not recognize is provided by a client, a random shared secret will be generated in such a way that a client should not be able to tell the difference between the identifier not being known and the secret being wrong. This can help protect against some username probing attacks. If it returns false, the server will instead send an `unknown_psk_identity` alert when an unknown identifier is used.

Default: false

u32bit **session_ticket_lifetime**() **const**
Return the lifetime of session tickets. Each session includes the start time. Sessions resumptions using tickets older than `session_ticket_lifetime` seconds will fail, forcing a full renegotiation.

Default: 86400 seconds (1 day)

15.7 TLS Ciphersuites

class TLS::**Ciphersuite**

uint16_t **ciphersuite_code**() **const**
: Return the numerical code for this ciphersuite

std::string **to_string**() **const**
: Return the full name of ciphersuite (for example "RSA_WITH_RC4_128_SHA" or "ECDHE_RSA_WITH_AES_128_GCM_SHA256")

std::string **kex_algo**() **const**
: Return the key exchange algorithm of this ciphersuite

std::string **sig_algo**() **const**
: Return the signature algorithm of this ciphersuite

std::string **cipher_algo**() **const**
: Return the cipher algorithm of this ciphersuite

std::string **mac_algo**() **const**
: Return the authentication algorithm of this ciphersuite

15.8 TLS Alerts

A TLS::Alert is passed to every invocation of a channel's *alert_cb*.

class TLS::**Alert**

is_valid() **const**
: Return true if this alert is not a null alert

is_fatal() **const**
: Return true if this alert is fatal. A fatal alert causes the connection to be immediately disconnected. Otherwise, the alert is a warning and the connection remains valid.

Type **type**() **const**
: Returns the type of the alert as an enum

std::string **type_string**()
: Returns the type of the alert as a string

15.9 TLS Protocol Version

TLS has several different versions with slightly different behaviors. The TLS::Protocol_Version class represents a specific version:

class TLS::**Protocol_Version**

enum Version_Code
: TLS_V10, TLS_V11, TLS_V12, DTLS_V10, DTLS_V12

Protocol_Version(*Version_Code named_version*)
: Create a specific version

uint8_t **major_version**() **const**
: Returns major number of the protocol version

uint8_t **minor_version**() **const**
: Returns minor number of the protocol version

std::string **to_string**() **const**
: Returns string description of the version, for instance "TLS v1.1" or "DTLS v1.0".

static *Protocol_Version* **latest_tls_version**()
: Returns the latest version of the TLS protocol known to the library (currently TLS v1.2)

static *Protocol_Version* **latest_dtls_version**()
: Returns the latest version of the DTLS protocol known to the library (currently DTLS v1.2)

15.10 TLS Custom Curves

The supported_groups TLS extension is used in the client hello to advertise a list of supported elliptic curves and DH groups. The server subsequently selects one of the groups, which is supported by both endpoints. The groups are represented by their TLS identifier. This 2 Byte identifier is standardized for commonly used groups and curves. In addition, the standard reserves the identifiers 0xFE00 to 0xFEFF for custom groups or curves.

Using non standardized custom curves is however not recommended and can be a serious risk if an insecure curve is used. Still, it might be desired in some scenarios to use custom curves or groups in the TLS handshake.

To use custom curves with the Botan *TLS::Client* or *TLS::Server* the following additional adjustments have to be implemented as shown in the following code examples.

1. Registration of the custom curve
2. Implementation TLS callback `tls_decode_group_param`
3. Adjustment of the TLS policy by allowing the custom curve

15.10.1 Client Code Example

```
#include <botan/tls_client.h>
#include <botan/tls_callbacks.h>
#include <botan/tls_session_manager.h>
#include <botan/tls_policy.h>
#include <botan/auto_rng.h>
#include <botan/certstor.h>

#include <botan/ec_group.h>
#include <botan/oids.h>

/**
 * @brief Callbacks invoked by TLS::Channel.
 *
 * Botan::TLS::Callbacks is an abstract class.
 * For improved readability, only the functions that are mandatory
 * to implement are listed here. See src/lib/tls/tls_callbacks.h.
 */
class Callbacks : public Botan::TLS::Callbacks
{
```

CHAPTER

SIXTEEN

CREDENTIALS MANAGER

A `Credentials_Manager` is a way to abstract how the application stores credentials in a way that is usable by protocol implementations. Currently the main user is the *Transport Layer Security (TLS)* implementation.

class Credentials_Manager

std::vector<*X509_Certificate*> **trusted_certificate_authorities**(**const** std::string &*type*, **const** std::string &*context*)

Return the list of trusted certificate authorities.

When *type* is "tls-client", *context* will be the hostname of the server, or empty if the hostname is not known.

When *type* is "tls-server", the *context* will again be the hostname of the server, or empty if the client did not send a server name indicator. For TLS servers, these CAs are the ones trusted for signing of client certificates. If you do not want the TLS server to ask for a client cert, `trusted_certificate_authorities` should return an empty list for *type* "tls-server".

The default implementation returns an empty list.

std::vector<*X509_Certificate*> **find_cert_chain**(**const** std::vector<std::string> &*cert_key_types*, **const** std::vector<*X509_DN*> &*acceptable_CAs*, **const** std::string &*type*, **const** std::string &*context*)

Return the certificate chain to use to identify ourselves. The `acceptable_CAs` parameter gives a list of CAs the peer trusts. This may be empty.

std::vector<*X509_Certificate*> **cert_chain**(**const** std::vector<std::string> &*cert_key_types*, **const** std::string &*type*, **const** std::string &*context*)

Return the certificate chain to use to identify ourselves. Starting in 2.5, prefer `find_cert_chain` which additionally provides the CA list.

std::vector<*X509_Certificate*> **cert_chain_single_type**(**const** std::string &*cert_key_type*, **const** std::string &*type*, **const** std::string &*context*)

Return the certificate chain to use to identifier ourselves, if we have one of type *cert_key_type* and we would like to use a certificate in this *type*/*context*.

Private_Key ***private_key_for**(**const** *X509_Certificate* &*cert*, **const** std::string &*type*, **const** std::string &*context*)

Return the private key for this certificate. The *cert* will be the leaf cert of a chain returned previously by `cert_chain` or `cert_chain_single_type`.

In versions before 1.11.34, there was an additional function on *Credentials_Manager*

This function has been replaced by *TLS::Callbacks::tls_verify_cert_chain*.

16.1 SRP Authentication

`Credentials_Manager` contains the hooks used by TLS clients and servers for SRP authentication.

bool **attempt_srp**(**const** std::string &*type*, **const** std::string &*context*)
Returns if we should consider using SRP for authentication

std::string **srp_identifier**(**const** std::string &*type*, **const** std::string &*context*)
Returns the SRP identifier we'd like to use (used by client)

std::string **srp_password**(**const** std::string &*type*, **const** std::string &*context*, **const** std::string &*identifier*)
Returns the password for *identifier* (used by client)

bool **srp_verifier**(**const** std::string &*type*, **const** std::string &*context*, **const** std::string &*identifier*, std::string &*group_name*, *BigInt* &*verifier*, std::vector<uint8_t> &*salt*, bool *generate_fake_on_unknown*)
Returns the SRP verifier information for *identifier* (used by server)

16.2 Preshared Keys

TLS and some other protocols support the use of pre shared keys for authentication.

SymmetricKey **psk**(**const** std::string &*type*, **const** std::string &*context*, **const** std::string &*identity*)
Return a symmetric key for use with *identity*

One important special case for `psk` is where *type* is "tls-server", *context* is "session-ticket" and *identity* is an empty string. If a key is returned for this case, a TLS server will offer session tickets to clients who can use them, and the returned key will be used to encrypt the ticket. The server is allowed to change the key at any time (though changing the key means old session tickets can no longer be used for resumption, forcing a full re-handshake when the client next connects). One simple approach to add support for session tickets in your server is to generate a random key the first time `psk` is called to retrieve the session ticket key, cache it for later use in the `Credentials_Manager`, and simply let it be thrown away when the process terminates.

See **RFC 4507** (https://tools.ietf.org/html/rfc4507.html) for more information about TLS session tickets.

std::string **psk_identity_hint**(**const** std::string &*type*, **const** std::string &*context*)
Returns an identity hint which may be provided to the client. This can help a client understand what PSK to use.

std::string **psk_identity**(**const** std::string &*type*, **const** std::string &*context*, **const** std::string &*identity_hint*)
Returns the identity we would like to use given this *type* and *context* and the optional *identity_hint*. Not all servers or protocols will provide a hint.

CHAPTER

SEVENTEEN

BIGINT

`BigInt` is Botan's implementation of a multiple-precision integer. Thanks to C++'s operator overloading features, using `BigInt` is often quite similar to using a native integer type. The number of functions related to `BigInt` is quite large, and not all of them are documented here. You can find the complete declarations in `botan/bigint.h` and `botan/numthry.h`.

class BigInt

BigInt (uint64_t *n*)
Create a BigInt with value *n*

BigInt (**const** std::string &*str*)
Create a BigInt from a string. By default decimal is expected. With an 0x prefix instead it is treated as hexadecimal.

BigInt (**const** uint8_t *buf*[], size_t *length*)
Create a BigInt from a binary array (big-endian encoding).

BigInt (*RandomNumberGenerator* &*rng*, size_t *bits*, bool *set_high_bit* = true)
Create a random BigInt of the specified size.

BigInt **operator+** (**const** *BigInt* &*x*, **const** *BigInt* &*y*)
Add `x` and `y` and return result.

BigInt **operator+** (**const** *BigInt* &*x*, word *y*)
Add `x` and `y` and return result.

BigInt **operator+** (word *x*, **const** *BigInt* &*y*)
Add `x` and `y` and return result.

BigInt **operator-** (**const** *BigInt* &*x*, **const** *BigInt* &*y*)
Subtract `y` from `x` and return result.

BigInt **operator-** (**const** *BigInt* &*x*, word *y*)
Subtract `y` from `x` and return result.

BigInt **operator*** (**const** *BigInt* &*x*, **const** *BigInt* &*y*)
Multiply `x` and `y` and return result.

BigInt **operator/** (**const** *BigInt* &*x*, **const** *BigInt* &*y*)
Divide `x` by `y` and return result.

BigInt **operator%** (**const** *BigInt* &*x*, **const** *BigInt* &*y*)
Divide `x` by `y` and return remainder.

word **operator%** (**const** *BigInt* &*x*, word *y*)
Divide `x` by `y` and return remainder.

word **operator<<** (**const** *BigInt* &*x*, size_t *n*)
Left shift `x` by `n` and return result.

word **operator>>** (**const** *BigInt* &*x*, size_t *n*)
Right shift `x` by `n` and return result.

BigInt &**operator+=** (**const** *BigInt* &*y*)
Add y to `*this`

BigInt &**operator+=** (word *y*)
Add y to `*this`

BigInt &**operator-=** (**const** *BigInt* &*y*)
Subtract y from `*this`

BigInt &**operator-=** (word *y*)
Subtract y from `*this`

BigInt &**operator*=** (**const** *BigInt* &*y*)
Multiply `*this` with y

BigInt &**operator*=** (word *y*)
Multiply `*this` with y

BigInt &**operator/=** (**const** *BigInt* &*y*)
Divide `*this` by y

BigInt &**operator%=** (**const** *BigInt* &*y*)
Divide `*this` by y and set `*this` to the remainder.

word **operator%=** (word *y*)
Divide `*this` by y and set `*this` to the remainder.

word **operator<<=** (size_t *shift*)
Left shift `*this` by *shift* bits

word **operator>>=** (size_t *shift*)
Right shift `*this` by *shift* bits

BigInt &**operator++** ()
Increment `*this` by 1

BigInt &**operator--** ()
Decrement `*this` by 1

BigInt **operator++** (int)
Postfix increment `*this` by 1

BigInt **operator--** (int)
Postfix decrement `*this` by 1

BigInt **operator-** () **const**
Negation operator

bool **operator!** () **const**
Return true unless `*this` is zero

void **clear** ()
Set `*this` to zero

size_t **bytes** () **const**
Return number of bytes need to represent value of `*this`

size_t **bits**() **const**
Return number of bits need to represent value of `*this`

bool **is_even**() **const**
Return true if `*this` is even

bool **is_odd**() **const**
Return true if `*this` is odd

bool **is_nonzero**() **const**
Return true if `*this` is not zero

bool **is_zero**() **const**
Return true if `*this` is zero

void **set_bit**(size_t *n*)
Set bit *n* of `*this`

void **clear_bit**(size_t *n*)
Clear bit *n* of `*this`

bool **get_bit**(size_t *n*) **const**
Get bit *n* of `*this`

uint32_t **to_u32bit**() **const**
Return value of `*this` as a 32-bit integer, if possible. If the integer is negative or not in range, an exception is thrown.

bool **is_negative**() **const**
Return true if `*this` is negative

bool **is_positive**() **const**
Return true if `*this` is negative

BigInt **abs**() **const**
Return absolute value of `*this`

void **binary_encode**(uint8_t *buf*[]) **const**
Encode this BigInt as a big-endian integer. The sign is ignored.

void **binary_decode**(uint8_t *buf*[])
Decode this BigInt as a big-endian integer.

17.1 Number Theory

Number theoretic functions available include:

BigInt **gcd**(*BigInt x*, *BigInt y*)
Returns the greatest common divisor of x and y

BigInt **lcm**(*BigInt x*, *BigInt y*)
Returns an integer z which is the smallest integer such that z % x == 0 and z % y == 0

BigInt **jacobi**(*BigInt a*, *BigInt n*)
Return Jacobi symbol of (aln).

BigInt **inverse_mod**(*BigInt x*, *BigInt m*)
Returns the modular inverse of x modulo m, that is, an integer y such that (x*y) % m == 1. If no such y exists, returns zero.

BigInt **power_mod**(*BigInt b*, *BigInt x*, *BigInt m*)

Returns b to the xth power modulo m. If you are doing many exponentiations with a single fixed modulus, it is faster to use a `Power_Mod` implementation.

BigInt **ressol**(*BigInt x*, *BigInt p*)

Returns the square root modulo a prime, that is, returns a number y such that (y*y) % p == x. Returns -1 if no such integer exists.

bool **is_prime**(*BigInt n*, *RandomNumberGenerator* &*rng*, size_t *prob* = 56, double *is_random* = false)

Test *n* for primality using a probabilistic algorithm (Miller-Rabin). With this algorithm, there is some non-zero probability that true will be returned even if *n* is actually composite. Modifying *prob* allows you to decrease the chance of such a false positive, at the cost of increased runtime. Sufficient tests will be run such that the chance *n* is composite is no more than 1 in 2^{prob}. Set *is_random* to true if (and only if) *n* was randomly chosen (ie, there is no danger it was chosen maliciously) as far fewer tests are needed in that case.

BigInt **random_prime**(*RandomNumberGenerator* &*rng*, size_t *bits*, *BigInt coprime* = 1, size_t *equiv* = 1, size_t *equiv_mod* = 2)

Return a random prime number of `bits` bits long that is relatively prime to `coprime`, and equivalent to `equiv` modulo `equiv_mod`.

CHAPTER

EIGHTEEN

KEY DERIVATION FUNCTIONS

Key derivation functions are used to turn some amount of shared secret material into uniform random keys suitable for use with symmetric algorithms. An example of an input which is useful for a KDF is a shared secret created using Diffie-Hellman key agreement.

class KDF

secure_vector<uint8_t> **derive_key**(size_t *key_len*, **const** std::vector<uint8_t> &*secret*, **const** std::string &*salt* = "") **const**

secure_vector<uint8_t> **derive_key**(size_t *key_len*, **const** std::vector<uint8_t> &*secret*, **const** std::vector<uint8_t> &*salt*) **const**

secure_vector<uint8_t> **derive_key**(size_t *key_len*, **const** std::vector<uint8_t> &*secret*, **const** uint8_t **salt*, size_t *salt_len*) **const**

secure_vector<uint8_t> **derive_key**(size_t *key_len*, **const** uint8_t **secret*, size_t *secret_len*, **const** std::string &*salt*) **const**

All variations on the same theme. Deterministically creates a uniform random value from *secret* and *salt*. Typically *salt* is a label or identifier, such as a session id.

You can create a *KDF* using

KDF ***get_kdf**(**const** std::string &*algo_spec*)

18.1 Available KDFs

Botan includes many different KDFs simply because different protocols and standards have created subtly different approaches to this problem. For new code, use HKDF which is conservative, well studied, widely implemented and NIST approved.

18.1.1 HKDF

Defined in RFC 5869, HKDF uses HMAC to process inputs. Also available are variants HKDF-Extract and HKDF-Expand. HKDF is the combined Extract+Expand operation. Use the combined HKDF unless you need compatibility with some other system.

Available if `BOTAN_HAS_HKDF` is defined.

18.1.2 KDF2

KDF2 comes from IEEE 1363. It uses a hash function.

Available if BOTAN_HAS_KDF2 is defined.

18.1.3 KDF1-18033

KDF1 from ISO 18033-2. Very similar to (but incompatible with) KDF2.

Available if BOTAN_HAS_KDF1_18033 is defined.

18.1.4 KDF1

KDF1 from IEEE 1363. It can only produce an output at most the length of the hash function used.

Available if BOTAN_HAS_KDF1 is defined.

18.1.5 X9.42 PRF

A KDF from ANSI X9.42. Sometimes used for Diffie-Hellman.

Available if BOTAN_HAS_X942_PRF is defined.

18.1.6 SP800-108

KDFs from NIST SP 800-108. Variants include "SP800-108-Counter", "SP800-108-Feedback" and "SP800-108-Pipeline".

Available if BOTAN_HAS_SP800_108 is defined.

18.1.7 SP800-56A

KDF from NIST SP 800-56A.

Available if BOTAN_HAS_SP800_56A is defined.

18.1.8 SP800-56C

KDF from NIST SP 800-56C.

Available if BOTAN_HAS_SP800_56C is defined.

CHAPTER

NINETEEN

PASSWORD BASED KEY DERIVATION

Often one needs to convert a human readable password into a cryptographic key. It is useful to slow down the computation of these computations in order to reduce the speed of brute force search, thus they are parameterized in some way which allows their required computation to be tuned.

19.1 PBKDF

PBKDF is the older API for this functionality, presented in header `pbkdf.h`. It does not support Scrypt, nor will it be able to support other future hashes (such as Argon2) that may be added in the future. In addition, this API requires the passphrase be entered as a `std::string`, which means the secret will be stored in memory that will not be zeroed.

class PBKDF

void **pbkdf_iterations**(uint8_t *out*[], size_t *out_len*, **const** std::string &*passphrase*, **const** uint8_t *salt*[], size_t *salt_len*, size_t *iterations*) **const**

Run the PBKDF algorithm for the specified number of iterations, with the given salt, and write output to the buffer.

void **pbkdf_timed**(uint8_t *out*[], size_t *out_len*, **const** std::string &*passphrase*, **const** uint8_t *salt*[], size_t *salt_len*, std::chrono::milliseconds *msec*, size_t &*iterations*) **const**

Choose (via short run-time benchmark) how many iterations to perform in order to run for roughly msec milliseconds. Writes the number of iterations used to reference argument.

OctetString **derive_key**(size_t *output_len*, **const** std::string &*passphrase*, **const** uint8_t **salt*, size_t *salt_len*, size_t *iterations*) **const**

Computes a key from *passphrase* and the *salt* (of length *salt_len* bytes) using an algorithm-specific interpretation of *iterations*, producing a key of length *output_len*.

Use an iteration count of at least 10000. The salt should be randomly chosen by a good random number generator (see *Random Number Generators* for how), or at the very least unique to this usage of the passphrase.

If you call this function again with the same parameters, you will get the same key.

19.2 PasswordHash

New in version 2.8.0.

This API has two classes, one representing the algorithm (such as "PBKDF2(SHA-256)", or "Scrypt") and the other representing a specific instance of the problem which is fully specified (say "Scrypt" with N=8192,r=64,p=8).

class PasswordHash

void **derive_key**(uint8_t *out*[], size_t *out_len*, **const** char **password*, **const** size_t *password_len*, **const** uint8_t *salt*[], size_t *salt_len*) **const**
Derive a key, placing it into output

std::string **to_string**() **const**
Return a descriptive string including the parameters (iteration count, etc)

The `PasswordHashFamily` creates specific instances of `PasswordHash`:

class PasswordHashFamily

static std::unique_ptr<*PasswordHashFamily*> **create**(**const** std::string &*what*)
For example "PBKDF2(SHA-256)", "Scrypt", "OpenPGP-S2K(SHA-384)". Returns null if not available.

std::unique_ptr<*PasswordHash*> **default_params**() **const**
Create a default instance of the password hashing algorithm. Be warned the value returned here may change from release to release.

std::unique_ptr<*PasswordHash*> **tune**(size_t *output_len*, std::chrono::milliseconds *msec*) **const**
Return a password hash instance tuned to run for approximately `msec` milliseconds when producing an output of length `output_len`. (Accuracy may vary, use the command line utility `botan pbkdf_tune` to check.)

std::unique_ptr<*PasswordHash*> **from_configuration**(size_t *i1*, size_t *i2* = 0, size_t *i3* = 0, size_t *i4* = 0, **const** char **cfg_str* = nullptr) **const**
Return a new password hash instance based on some number of integer and string parameters. Any values not used by a particular scheme should be set to zero/null.

19.3 Available Schemes

19.3.1 PBKDF2

PBKDF2 is the "standard" password derivation scheme, widely implemented in many different libraries. It uses HMAC internally.

19.3.2 Scrypt

Scrypt is a relatively newer design which is "memory hard" - in addition to requiring large amounts of CPU power it uses a large block of memory to compute the hash. This makes brute force attacks using ASICs substantially more expensive.

Scrypt is not supported through *PBKDF*, only *PasswordHash*, starting in 2.8.0. In addition, starting in version 2.7.0, scrypt is available with this function:

void **scrypt**(uint8_t *output*[], size_t *output_len*, **const** std::string &*password*, **const** uint8_t *salt*[], size_t *salt_len*, size_t *N*, size_t *r*, size_t *p*)
Computes the Scrypt using the password and salt, and produces an output of arbitrary length.

The N, r, p parameters control how much work and memory Scrypt uses. N is the primary control of the workfactor, and must be a power of 2. For interactive logins use 32768, for protection of secret keys or backups use 1048576.

The r parameter controls how 'wide' the internal hashing operation is. It also increases the amount of memory that is used. Values from 1 to 8 are reasonable.

Setting p parameter to greater than one splits up the work in a way that up to p processors can work in parallel.

As a general recommendation, use N=32768, r=8, p=1

19.3.3 OpenPGP S2K

Warning: The OpenPGP algorithm is weak and strange, and should be avoided unless implementing OpenPGP.

There are some oddities about OpenPGP's S2K algorithms that are documented here. For one thing, it uses the iteration count in a strange manner; instead of specifying how many times to iterate the hash, it tells how many *bytes* should be hashed in total (including the salt). So the exact iteration count will depend on the size of the salt (which is fixed at 8 bytes by the OpenPGP standard, though the implementation will allow any salt size) and the size of the passphrase.

To get what OpenPGP calls "Simple S2K", set iterations to 0, and do not specify a salt. To get "Salted S2K", again leave the iteration count at 0, but give an 8-byte salt. "Salted and Iterated S2K" requires an 8-byte salt and some iteration count (this should be significantly larger than the size of the longest passphrase that might reasonably be used; somewhere from 1024 to 65536 would probably be about right). Using both a reasonably sized salt and a large iteration count is highly recommended to prevent password guessing attempts.

19.3.4 PBKDF1

PBKDF1 is an old scheme that can only produce an output length at most as long as the hash function. It is deprecated and will be removed in a future release. It is not supported through `PasswordHash`.

CHAPTER

TWENTY

AES KEY WRAPPING

NIST specifies two mechanisms for wrapping (encrypting) symmetric keys using another key. The first (and older, more widely supported) method requires the input be a multiple of 8 bytes long. The other allows any length input, though only up to 2**32 bytes.

These algorithms are described in NIST SP 800-38F, and RFCs 3394 and 5649.

This API, defined in `nist_keywrap.h`, first became available in version 2.4.0

These functions take an arbitrary 128-bit block cipher object, which must already have been keyed with the key encryption key. NIST only allows these functions with AES, but any 128-bit cipher will do and some other implementations (such as in OpenSSL) do also allow other ciphers. Use AES for best interop.

std::vector<uint8_t> **nist_key_wrap**(**const** uint8_t *input*[], size_t *input_len*, **const** *BlockCipher* &*bc*)

This performs KW (key wrap) mode. The input must be a multiple of 8 bytes long.

secure_vector<uint8_t> **nist_key_unwrap**(**const** uint8_t *input*[], size_t *input_len*, **const** *BlockCipher* &*bc*)

This unwraps the result of nist_key_wrap, or throw Integrity_Failure on error.

std::vector<uint8_t> **nist_key_wrap_padded**(**const** uint8_t *input*[], size_t *input_len*, **const** *BlockCipher* &*bc*)

This performs KWP (key wrap with padding) mode. The input can be any length.

secure_vector<uint8_t> **nist_key_unwrap_padded**(**const** uint8_t *input*[], size_t *input_len*, **const** *BlockCipher* &*bc*)

This unwraps the result of nist_key_wrap_padded, or throws Integrity_Failure on error.

20.1 RFC 3394 Interface

This is an older interface that was first available (with slight changes) in 1.10, and available in its current form since 2.0 release. It uses a 128-bit, 192-bit, or 256-bit key to encrypt an input key. AES is always used. The input must be a multiple of 8 bytes; if not an exception is thrown.

This interface is defined in `rfc3394.h`.

secure_vector<uint8_t> **rfc3394_keywrap**(**const** secure_vector<uint8_t> &*key*, **const** SymmetricKey &*kek*)

Wrap the input key using kek (the key encryption key), and return the result. It will be 8 bytes longer than the input key.

secure_vector<uint8_t> **rfc3394_keyunwrap**(**const** secure_vector<uint8_t> &*key*, **const** SymmetricKey &*kek*)

Unwrap a key wrapped with rfc3394_keywrap.

CHAPTER

TWENTYONE

PASSWORD HASHING

Storing passwords for user authentication purposes in plaintext is the simplest but least secure method; when an attacker compromises the database in which the passwords are stored, they immediately gain access to all of them. Often passwords are reused among multiple services or machines, meaning once a password to a single service is known an attacker has a substantial head start on attacking other machines.

The general approach is to store, instead of the password, the output of a one way function of the password. Upon receiving an authentication request, the authenticating party can recompute the one way function and compare the value just computed with the one that was stored. If they match, then the authentication request succeeds. But when an attacker gains access to the database, they only have the output of the one way function, not the original password.

Common hash functions such as SHA-256 are one way, but used alone they have problems for this purpose. What an attacker can do, upon gaining access to such a stored password database, is hash common dictionary words and other possible passwords, storing them in a list. Then he can search through his list; if a stored hash and an entry in his list match, then he has found the password. Even worse, this can happen *offline*: an attacker can begin hashing common passwords days, months, or years before ever gaining access to the database. In addition, if two users choose the same password, the one way function output will be the same for both of them, which will be visible upon inspection of the database.

There are two solutions to these problems: salting and iteration. Salting refers to including, along with the password, a randomly chosen value which perturbs the one way function. Salting can reduce the effectiveness of offline dictionary generation, because for each potential password, an attacker would have to compute the one way function output for all possible salts. It also prevents the same password from producing the same output, as long as the salts do not collide. Choosing n-bit salts randomly, salt collisions become likely only after about 2:sup:*(n/2)* salts have been generated. Choosing a large salt (say 80 to 128 bits) ensures this is very unlikely. Note that in password hashing salt collisions are unfortunate, but not fatal - it simply allows the attacker to attack those two passwords in parallel easier than they would otherwise be able to.

The other approach, iteration, refers to the general technique of forcing multiple one way function evaluations when computing the output, to slow down the operation. For instance if hashing a single password requires running SHA-256 100,000 times instead of just once, that will slow down user authentication by a factor of 100,000, but user authentication happens quite rarely, and usually there are more expensive operations that need to occur anyway (network and database I/O, etc). On the other hand, an attacker who is attempting to break a database full of stolen password hashes will be seriously inconvenienced by a factor of 100,000 slowdown; they will be able to only test at a rate of .0001% of what they would without iterations (or, equivalently, will require 100,000 times as many zombie botnet hosts).

Memory usage while checking a password is also a consideration; if the computation requires using a certain minimum amount of memory, then an attacker can become memory-bound, which may in particular make customized cracking hardware more expensive. Some password hashing designs, such as scrypt, explicitly attempt to provide this. The bcrypt approach requires over 4 KiB of RAM (for the Blowfish key schedule) and may also make some hardware attacks more expensive.

Botan provides two techniques for password hashing, bcrypt and passhash9.

21.1 Bcrypt

Bcrypt (https://www.usenix.org/legacy/event/usenix99/provos/provos.pdf) is a password hashing scheme originally designed for use in OpenBSD, but numerous other implementations exist. It is made available by including `bcrypt.h`.

It has the advantage that it requires a small amount (4K) of fast RAM to compute, which can make hardware password cracking somewhat more expensive.

Bcrypt provides outputs that look like this:

```
"$2a$12$7KIYdyv8Bp32WAvc.7YvI.wvRlyVn0HP/EhPmmOyMQA4YKxINO0p2"
```

Note: Due to the design of bcrypt, the password is effectively truncated at 72 characters; further characters are ignored and do not change the hash. To support longer passwords, one common approach is to pre-hash the password with SHA-256, then run bcrypt using the hex or base64 encoding of the hash as the password. (Many bcrypt implementations truncate the password at the first NULL character, so hashing the raw binary SHA-256 may cause problems. Botan's bcrypt implementation will hash whatever values are given in the `std::string` including any embedded NULLs so this is not an issue, but might cause interop problems if another library needs to validate the password hashes.)

---

std::string **generate_bcrypt**(**const** std::string &*password*, *RandomNumberGenerator* &*rng*, uint16_t *work_factor* = 12, char *bcrypt_version* = "a")

Takes the password to hash, a rng, and a work factor. The resulting password hash is returned as a string.

Higher work factors increase the amount of time the algorithm runs, increasing the cost of cracking attempts. The increase is exponential, so a work factor of 12 takes roughly twice as long as work factor 11. The default work factor was set to 10 up until the 2.8.0 release.

It is recommended to set the work factor as high as your system can tolerate (from a performance and latency perspective) since higher work factors greatly improve the security against GPU-based attacks. For example, for protecting high value administrator passwords, consider using work factor 15 or 16; at these work factors each bcrypt computation takes several seconds. Since admin logins will be relatively uncommon, it might be acceptable for each login attempt to take some time. As of 2018, a good password cracking rig (with 8 NVIDIA 1080 cards) can attempt about 1 billion bcrypt computations per month for work factor 13. For work factor 12, it can do twice as many. For work factor 15, it can do only one quarter as many attempts.

Due to bugs affecting various implementations of bcrypt, several different variants of the algorithm are defined. As of 2.7.0 Botan supports generating (or checking) the 2a, 2b, and 2y variants. Since Botan has never been affected by any of the bugs which necessitated these version upgrades, all three versions are identical beyond the version identifier. Which variant to use is controlled by the `bcrypt_version` argument.

The bcrypt work factor must be at least 4 (though at this work factor bcrypt is not very secure). The bcrypt format allows up to 31, but Botan currently rejects all work factors greater than 18 since even that work factor requires roughly 15 seconds of computation on a fast machine.

bool **check_bcrypt**(**const** std::string &*password*, **const** std::string &*hash*)

Takes a password and a bcrypt output and returns true if the password is the same as the one that was used to generate the bcrypt hash.

21.2 Passhash9

Botan also provides a password hashing technique called passhash9, in `passhash9.h`, which is based on PBKDF2.

Passhash9 hashes look like:

```
"$9$AAAKxwMGNPSdPkOKJS07Xutm3+1Cr3ytmbnkjO6LjHzCMcMQXvcT"
```

This function should be secure with the proper parameters, and will remain in the library for the foreseeable future, but it is specific to Botan rather than being a widely used password hash. Prefer bcrypt.

Warning: This password format string ("9") conflicts with the format used for scrypt password hashes on Cisco systems.

std::string **generate_passhash9**(**const** std::string &*password*, *RandomNumberGenerator* &*rng*, uint16_t *work_factor* = 15, uint8_t *alg_id* = 4)

Functions much like `generate_bcrypt`. The last parameter, `alg_id`, specifies which PRF to use. Currently defined values are 0: HMAC(SHA-1), 1: HMAC(SHA-256), 2: CMAC(Blowfish), 3: HMAC(SHA-384), 4: HMAC(SHA-512)

The work factor must be greater than zero and less than 512. This performs 10000 * `work_factor` PBKDF2 iterations, using 96 bits of salt taken from `rng`. Using work factor of 10 or more is recommended.

bool **check_passhash9**(**const** std::string &*password*, **const** std::string &*hash*)

Functions much like `check_bcrypt`

CHAPTER

TWENTYTWO

CRYPTOBOX

22.1 Encryption using a passphrase

New in version 1.8.6.

This is a set of simple routines that encrypt some data using a passphrase. There are defined in the header *cryptobox.h*, inside namespace *Botan::CryptoBox*.

It generates cipher and MAC keys using 8192 iterations of PBKDF2 with HMAC(SHA-512), then encrypts using Serpent in CTR mode and authenticates using a HMAC(SHA-512) mac of the ciphertext, truncated to 160 bits.

std::string **encrypt**(**const** uint8_t *input*[], size_t *input_len*, **const** std::string &*passphrase*, *RandomNumberGenerator* &*rng*)
Encrypt the contents using *passphrase*.

std::string **decrypt**(**const** uint8_t *input*[], size_t *input_len*, **const** std::string &*passphrase*)
Decrypts something encrypted with encrypt.

std::string **decrypt**(**const** std::string &*input*, **const** std::string &*passphrase*)
Decrypts something encrypted with encrypt.

CHAPTER

TWENTYTHREE

SECURE REMOTE PASSWORD

The library contains an implementation of the SRP6-a (http://srp.stanford.edu/design.html) password authenticated key exchange protocol in `srp6.h`.

A SRP client provides what is called a SRP *verifier* to the server. This verifier is based on a password, but the password cannot be easily derived from the verifier. Later, the client and server can perform an SRP exchange, which results in a shared key.

SRP works in a discrete logarithm group. Special parameter sets for SRP6 are defined, denoted in the library as "modp/srp/<size>", for example "modp/srp/2048".

Warning: While knowledge of the verifier does not easily allow an attacker to get the raw password, they could still use the verifier to impersonate the server to the client, so verifiers should be carefully protected.

BigInt **generate_srp6_verifier**(**const** std::string &*identifier*, **const** std::string &*password*, **const** std::vector<uint8_t> &*salt*, **const** std::string &*group_id*, **const** std::string &*hash_id*)

Generates a new verifier using the specified password and salt. This is stored by the server. The salt must also be stored.

std::string **srp6_group_identifier**(**const** *BigInt* &*N*, **const** *BigInt* &*g*)

class SRP6_Server_Session

BigInt **step1**(**const** *BigInt* &*v*, **const** std::string &*group_id*, **const** std::string &*hash_id*, *RandomNumberGenerator* &*rng*)

Takes a verifier (generated by generate_srp6_verifier) along with the group_id (which must match

SymmetricKey **step2**(**const** *BigInt* &*A*)

Takes the parameter A generated by srp6_client_agree, and return the shared secret key.

std::pair<*BigInt*, SymmetricKey> **srp6_client_agree**(**const** std::string &*username*, **const** std::string &*password*, **const** std::string &*group_id*, **const** std::string &*hash_id*, **const** std::vector<uint8_t> &*salt*, **const** *BigInt* &*B*, *RandomNumberGenerator* &*rng*)

The client receives these parameters from the server, except for the username and password which are provided by the user. The parameter B is the output of *step1*.

The client agreement step outputs a shared symmetric key along with the parameter A which is returned to the server (and allows it the compute the shared key).

TWENTYFOUR

PSK DATABASE

New in version 2.4.0.

Many applications need to store pre-shared keys (hereafter PSKs) for authentication purposes.

An abstract interface to PSK stores is provided in `psk_db.h`

class PSK_Database

bool **is_encrypted**() **const**
: Returns true if (at least) the PSKs themselves are encrypted. Returns false if PSKs are stored in plaintext.

std::set<std::string> **list_names**() **const**
: Return the set of valid names stored in the database, ie values for which `get` will return a value.

void **set**(**const** std::string &*name*, **const** uint8_t *psk*[], size_t *psk_len*)
: Save a PSK. If `name` already exists, the current value will be overwritten.

secure_vector<uint8_t> **get**(**const** std::string &*name*) **const**
: Return a value saved with `set`. Throws an exception if `name` doesn't exist.

void **remove**(**const** std::string &*name*)
: Remove `name` from the database. If `name` doesn't exist, ignores the request.

void **set_str**(**const** std::string &*name*, **const** std::string &*psk*)
: Like `set` but accepts the psk as a string (eg for a password).

template<typename **Alloc**>
void **set_vec**(**const** std::string &*name*, **const** std::vector<uint8_t, *Alloc*> &*psk*)
: Like `set` but accepting a vector.

The same header also provides a specific instantiation of `PSK_Database` which encrypts both names and PSKs. It must be subclassed to provide the storage.

class Encrypted_PSK_Database : **public** *PSK_Database*

Encrypted_PSK_Database(**const** secure_vector<uint8_t> &*master_key*)
: Initializes or opens a PSK database. The master key is used the secure the contents. It may be of any length. If encrypting PSKs under a passphrase, use a suitable key derivation scheme (such as PBKDF2) to derive the secret key. If the master key is lost, all PSKs stored are unrecoverable.

  Both names and values are encrypted using NIST key wrapping (see NIST SP800-38F) with AES-256. First the master key is used with HMAC(SHA-256) to derive two 256-bit keys, one for encrypting all names and the other to key an instance of HMAC(SHA-256). Values are each encrypted under an individual key created by hashing the encrypted name with HMAC. This associates the encrypted key with the name, and prevents an attacker with write access to the data store from taking an encrypted key associated with one entity and copying it to another entity.

Names and PSKs are both padded to the next multiple of 8 bytes, providing some obfuscation of the length.

One artifact of the names being encrypted is that is is possible to use multiple different master keys with the same underlying storage. Each master key will be responsible for a subset of the keys. An attacker who knows one of the keys will be able to tell there are other values encrypted under another key.

virtual void **kv_set**(**const** std::string &*index*, **const** std::string &*value*) = 0
Save an encrypted value. Both `index` and `value` will be non-empty base64 encoded strings.

virtual std::string **kv_get**(**const** std::string &*index*) **const** = 0
Return a value saved with `kv_set`, or return the empty string.

virtual void **kv_del**(**const** std::string &*index*) = 0
Remove a value saved with `kv_set`.

virtual std::set<std::string> **kv_get_all**() **const** = 0
Return all active names (ie values for which `kv_get` will return a non-empty string).

A subclass of `Encrypted_PSK_Database` which stores data in a SQL database is also available. This class is declared in `psk_db_sql.h`:

class Encrypted_PSK_Database_SQL : **public** *Encrypted_PSK_Database*

Encrypted_PSK_Database_SQL(**const** secure_vector<uint8_t> &*master_key*, std::shared_ptr<SQL_Database> *db*, **const** std::string &*table_name*)
Creates or uses the named table in `db`. The SQL schema of the table is `(psk_name TEXT PRIMARY KEY, psk_value TEXT)`.

CHAPTER

TWENTYFIVE

PIPE/FILTER MESSAGE PROCESSING

Note: The system described below provides a message processing system with a straightforward API. However it makes many extra memory copies and allocations than would otherwise be required, and also tends to make applications using it somewhat opaque because it is not obvious what this or that Pipe& object actually does (type of operation, number of messages output (if any!), and so on), whereas using say a HashFunction or AEAD_Mode provides a much better idea in the code of what operation is occurring.

This filter interface is no longer used within the library itself (outside a few dusty corners) and will likely not see any further major development. However it will remain included because the API is often convenient and many applications use it.

Many common uses of cryptography involve processing one or more streams of data. Botan provides services that make setting up data flows through various operations, such as compression, encryption, and base64 encoding. Each of these operations is implemented in what are called *filters* in Botan. A set of filters are created and placed into a *pipe*, and information "flows" through the pipe until it reaches the end, where the output is collected for retrieval. If you're familiar with the Unix shell environment, this design will sound quite familiar.

Here is an example that uses a pipe to base64 encode some strings:

```
Pipe pipe(new Base64_Encoder); // pipe owns the pointer
pipe.start_msg();
pipe.write("message 1");
pipe.end_msg(); // flushes buffers, increments message number

// process_msg(x) is start_msg() && write(x) && end_msg()
pipe.process_msg("message2");

std::string m1 = pipe.read_all_as_string(0); // "message1"
std::string m2 = pipe.read_all_as_string(1); // "message2"
```

Byte streams in the pipe are grouped into messages; blocks of data that are processed in an identical fashion (ie, with the same sequence of filter operations). Messages are delimited by calls to `start_msg` and `end_msg`. Each message in a pipe has its own identifier, which currently is an integer that increments up from zero.

The `Base64_Encoder` was allocated using `new`; but where was it deallocated? When a filter object is passed to a `Pipe`, the pipe takes ownership of the object, and will deallocate it when it is no longer needed.

There are two different ways to make use of messages. One is to send several messages through a `Pipe` without changing the `Pipe` configuration, so you end up with a sequence of messages; one use of this would be to send a sequence of identically encrypted UDP packets, for example (note that the *data* need not be identical; it is just that each is encrypted, encoded, signed, etc in an identical fashion). Another is to change the filters that are used in the `Pipe` between each message, by adding or removing filters; functions that let you do this are documented in the Pipe API section.

Botan has about 40 filters that perform different operations on data. Here's code that uses one of them to encrypt a string with AES:

```
AutoSeeded_RNG rng,
SymmetricKey key(rng, 16); // a random 128-bit key
InitializationVector iv(rng, 16); // a random 128-bit IV

// The algorithm we want is specified by a string
Pipe pipe(get_cipher("AES-128/CBC", key, iv, ENCRYPTION));

pipe.process_msg("secrets");
pipe.process_msg("more secrets");

secure_vector<uint8_t> c1 = pipe.read_all(0);

uint8_t c2[4096] = { 0 };
size_t got_out = pipe.read(c2, sizeof(c2), 1);
// use c2[0...got_out]
```

Note the use of `AutoSeeded_RNG`, which is a random number generator. If you want to, you can explicitly set up the random number generators and entropy sources you want to, however for 99% of cases `AutoSeeded_RNG` is preferable.

`Pipe` also has convenience methods for dealing with `std::iostream`. Here is an example of this, using the bzip2 compression filter:

```
std::ifstream in("data.bin", std::ios::binary)
std::ofstream out("data.bin.bz2", std::ios::binary)

Pipe pipe(new Compression_Filter("bzip2", 9));

pipe.start_msg();
in >> pipe;
pipe.end_msg();
out << pipe;
```

However there is a hitch to the code above; the complete contents of the compressed data will be held in memory until the entire message has been compressed, at which time the statement `out << pipe` is executed, and the data is freed as it is read from the pipe and written to the file. But if the file is very large, we might not have enough physical memory (or even enough virtual memory!) for that to be practical. So instead of storing the compressed data in the pipe for reading it out later, we divert it directly to the file:

```
std::ifstream in("data.bin", std::ios::binary)
std::ofstream out("data.bin.bz2", std::ios::binary)

Pipe pipe(new Compression_Filter("bzip2", 9), new DataSink_Stream(out));

pipe.start_msg();
in >> pipe;
pipe.end_msg();
```

This is the first code we've seen so far that uses more than one filter in a pipe. The output of the compressor is sent to the `DataSink_Stream`. Anything written to a `DataSink_Stream` is written to a file; the filter produces no output. As soon as the compression algorithm finishes up a block of data, it will send it along to the sink filter, which will immediately write it to the stream; if you were to call `pipe.read_all()` after `pipe.end_msg()`, you'd get an empty vector out. This is particularly useful for cases where you are processing a large amount of data, as it means you don't have to store everything in memory at once.

Here's an example using two computational filters:

```
AutoSeeded_RNG rng,
SymmetricKey key(rng, 32);
InitializationVector iv(rng, 16);

Pipe encryptor(get_cipher("AES/CBC/PKCS7", key, iv, ENCRYPTION),
               new Base64_Encoder);

encryptor.start_msg();
file >> encryptor;
encryptor.end_msg(); // flush buffers, complete computations
std::cout << encryptor;
```

You can read from a pipe while you are still writing to it, which allows you to bound the amount of memory that is in use at any one time. A common idiom for this is:

```
pipe.start_msg();
std::vector<uint8_t> buffer(4096); // arbitrary size
while(infile.good())
   {
   infile.read((char*)&buffer[0], buffer.size());
   const size_t got_from_infile = infile.gcount();
   pipe.write(buffer, got_from_infile);

   if(infile.eof())
      pipe.end_msg();

   while(pipe.remaining() > 0)
      {
      const size_t buffered = pipe.read(buffer, buffer.size());
      outfile.write((const char*)&buffer[0], buffered);
      }
   }
if(infile.bad() || (infile.fail() && !infile.eof()))
   throw Some_Exception();
```

25.1 Fork

It is common that you might receive some data and want to perform more than one operation on it (ie, encrypt it with Serpent and calculate the SHA-256 hash of the plaintext at the same time). That's where `Fork` comes in. `Fork` is a filter that takes input and passes it on to *one or more* filters that are attached to it. `Fork` changes the nature of the pipe system completely: instead of being a linked list, it becomes a tree or acyclic graph.

Each filter in the fork is given its own output buffer, and thus its own message. For example, if you had previously written two messages into a pipe, then you start a new one with a fork that has three paths of filter's inside it, you add three new messages to the pipe. The data you put into the pipe is duplicated and sent into each set of filter and the eventual output is placed into a dedicated message slot in the pipe.

Messages in the pipe are allocated in a depth-first manner. This is only interesting if you are using more than one fork in a single pipe. As an example, consider the following:

```
Pipe pipe(new Fork(
             new Fork(
                new Base64_Encoder,
```

(continues on next page)

(continued from previous page)

```
                new Fork(
                   NULL,
                   new Base64_Encoder
                   )
                ),
             new Hex_Encoder
             )
   );
```

In this case, message 0 will be the output of the first `Base64_Encoder`, message 1 will be a copy of the input (see below for how fork interprets NULL pointers), message 2 will be the output of the second `Base64_Encoder`, and message 3 will be the output of the `Hex_Encoder`. This results in message numbers being allocated in a top to bottom fashion, when looked at on the screen. However, note that there could be potential for bugs if this is not anticipated. For example, if your code is passed a filter, and you assume it is a "normal" one that only uses one message, your message offsets would be wrong, leading to some confusion during output.

If Fork's first argument is a null pointer, but a later argument is not, then Fork will feed a copy of its input directly through. Here's a case where that is useful:

```
// have std::string ciphertext, auth_code, key, iv, mac_key;

Pipe pipe(new Base64_Decoder,
          get_cipher("AES-128", key, iv, DECRYPTION),
          new Fork(
             0, // this message gets plaintext
             new MAC_Filter("HMAC(SHA-1)", mac_key)
          )
   );

pipe.process_msg(ciphertext);
std::string plaintext = pipe.read_all_as_string(0);
secure_vector<uint8_t> mac = pipe.read_all(1);

if(mac != auth_code)
   error();
```

Here we wanted to not only decrypt the message, but send the decrypted text through an additional computation, in order to compute the authentication code.

Any filters that are attached to the pipe after the fork are implicitly attached onto the first branch created by the fork. For example, let's say you created this pipe:

```
Pipe pipe(new Fork(new Hash_Filter("SHA-256"),
                   new Hash_Filter("SHA-512")),
          new Hex_Encoder);
```

And then called `start_msg`, inserted some data, then `end_msg`. Then `pipe` would contain two messages. The first one (message number 0) would contain the SHA-256 sum of the input in hex encoded form, and the other would contain the SHA-512 sum of the input in raw binary. In many situations you'll want to perform a sequence of operations on multiple branches of the fork; in which case, use the filter described in *Chain*.

25.2 Chain

A `Chain` filter creates a chain of filters and encapsulates them inside a single filter (itself). This allows a sequence of filters to become a single filter, to be passed into or out of a function, or to a `Fork` constructor.

You can call Chain's constructor with up to four Filter pointers (they will be added in order), or with an array of filter pointers and a size_t that tells Chain how many filters are in the array (again, they will be attached in order). Here's the example from the last section, using chain instead of relying on the implicit pass through the other version used:

```
Pipe pipe(new Fork(
               new Chain(new Hash_Filter("SHA-256"), new Hex_Encoder),
               new Hash_Filter("SHA-512")
               )
         );
```

25.3 Sources and Sinks

25.3.1 Data Sources

A DataSource is a simple abstraction for a thing that stores bytes. This type is used heavily in the areas of the API related to ASN.1 encoding/decoding. The following types are DataSource: Pipe, SecureQueue, and a couple of special purpose ones: DataSource_Memory and DataSource_Stream.

You can create a DataSource_Memory with an array of bytes and a length field. The object will make a copy of the data, so you don't have to worry about keeping that memory allocated. This is mostly for internal use, but if it comes in handy, feel free to use it.

A DataSource_Stream is probably more useful than the memory based one. Its constructors take either a std::istream or a std::string. If it's a stream, the data source will use the istream to satisfy read requests (this is particularly useful to use with std::cin). If the string version is used, it will attempt to open up a file with that name and read from it.

25.3.2 Data Sinks

A DataSink (in data_snk.h) is a Filter that takes arbitrary amounts of input, and produces no output. This means it's doing something with the data outside the realm of what Filter/Pipe can handle, for example, writing it to a file (which is what the DataSink_Stream does). There is no need for DataSink``s that write to a ``std::string or memory buffer, because Pipe can handle that by itself.

Here's a quick example of using a DataSink, which encrypts in.txt and sends the output to out.txt. There is no explicit output operation; the writing of out.txt is implicit:

```
DataSource_Stream in("in.txt");
Pipe pipe(get_cipher("AES-128/CTR-BE", key, iv),
          new DataSink_Stream("out.txt"));
pipe.process_msg(in);
```

A real advantage of this is that even if "in.txt" is large, only as much memory is needed for internal I/O buffers will be used.

25.4 The Pipe API

25.4.1 Initializing Pipe

By default, Pipe will do nothing at all; any input placed into the Pipe will be read back unchanged. Obviously, this has limited utility, and presumably you want to use one or more filters to somehow process the data. First, you can

choose a set of filters to initialize the `Pipe` via the constructor. You can pass it either a set of up to four filter pointers, or a pre-defined array and a length:

```
Pipe pipe1(new Filter1(/*args*/), new Filter2(/*args*/),
           new Filter3(/*args*/), new Filter4(/*args*/));
Pipe pipe2(new Filter1(/*args*/), new Filter2(/*args*/));

Filter* filters[5] = {
  new Filter1(/*args*/), new Filter2(/*args*/), new Filter3(/*args*/),
  new Filter4(/*args*/), new Filter5(/*args*/) /* more if desired... */
};
Pipe pipe3(filters, 5);
```

This is by far the most common way to initialize a `Pipe`. However, occasionally a more flexible initialization strategy is necessary; this is supported by 4 member functions. These functions may only be used while the pipe in question is not in use; that is, either before calling `start_msg`, or after `end_msg` has been called (and no new calls to `start_msg` have been made yet).

void `Pipe::prepend`(Filter **filter*)
: Calling `prepend` will put the passed filter first in the list of transformations. For example, if you prepend a filter implementing encryption, and the pipe already had a filter that hex encoded the input, then the next message processed would be first encrypted, and *then* hex encoded.

void `Pipe::append`(Filter **filter*)
: Like `prepend`, but places the filter at the end of the message flow. This doesn't always do what you expect if there is a fork.

void `Pipe::pop`()
: Removes the first filter in the flow.

void `Pipe::reset`()
: Removes all the filters that the pipe currently holds - it is reset to an empty/no-op state. Any data that is being retained by the pipe is retained after a `reset`, and `reset` does not affect message numbers (discussed later).

25.4.2 Giving Data to a Pipe

Input to a `Pipe` is delimited into messages, which can be read from independently (ie, you can read 5 bytes from one message, and then all of another message, without either read affecting any other messages).

void `Pipe::start_msg`()
: Starts a new message; if a message was already running, an exception is thrown. After this function returns, you can call `write`.

void `Pipe::write`(**const** uint8_t **input*, size_t *length*)

void `Pipe::write`(**const** std::vector<uint8_t> &*input*)

void `Pipe::write`(**const** std::string &*input*)

void `Pipe::write`(DataSource &*input*)

void `Pipe::write`(uint8_t *input*)
: All versions of `write` write the input into the filter sequence. If a message is not currently active, an exception is thrown.

void `Pipe::end_msg`()
: End the currently active message

Sometimes, you may want to do only a single write per message. In this case, you can use the `process_msg` series of functions, which start a message, write their argument into the pipe, and then end the message. In this case you would not make any explicit calls to `start_msg`/`end_msg`.

Pipes can also be used with the `>>` operator, and will accept a `std::istream`, or on Unix systems with the `fd_unix` module, a Unix file descriptor. In either case, the entire contents of the file will be read into the pipe.

25.4.3 Getting Output from a Pipe

Retrieving the processed data from a pipe is a bit more complicated, for various reasons. The pipe will separate each message into a separate buffer, and you have to retrieve data from each message independently. Each of the reader functions has a final parameter that specifies what message to read from. If this parameter is set to `Pipe::DEFAULT_MESSAGE`, it will read the current default message (`DEFAULT_MESSAGE` is also the default value of this parameter).

Functions in `Pipe` related to reading include:

size_t `Pipe::`**`read`**(uint8_t **out*, size_t *len*)
: Reads up to `len` bytes into `out`, and returns the number of bytes actually read.

size_t `Pipe::`**`peek`**(uint8_t **out*, size_t *len*)
: Acts exactly like *read*, except the data is not actually read; the next read will return the same data.

secure_vector<uint8_t> `Pipe::`**`read_all`**()
: Reads the entire message into a buffer and returns it

std::string `Pipe::`**`read_all_as_string`**()
: Like `read_all`, but it returns the data as a `std::string`. No encoding is done; if the message contains raw binary, so will the string.

size_t `Pipe::`**`remaining`**()
: Returns how many bytes are left in the message

Pipe::message_id `Pipe::`**`default_msg`**()
: Returns the current default message number

Pipe::message_id `Pipe::`**`message_count`**()
: Returns the total number of messages currently in the pipe

`Pipe::`**`set_default_msg`**(Pipe::message_id *msgno*)
: Sets the default message number (which must be a valid message number for that pipe). The ability to set the default message number is particularly important in the case of using the file output operations (<< with a `std::ostream` or Unix file descriptor), because there is no way to specify the message explicitly when using the output operator.

25.4.4 Pipe I/O for Unix File Descriptors

This is a minor feature, but it comes in handy sometimes. In all installations of the library, Botan's `Pipe` object overloads the << and >> operators for C++ iostream objects, which is usually more than sufficient for doing I/O.

However, there are cases where the iostream hierarchy does not map well to local 'file types', so there is also the ability to do I/O directly with Unix file descriptors. This is most useful when you want to read from or write to something like a TCP or Unix-domain socket, or a pipe, since for simple file access it's usually easier to just use C++'s file streams.

If `BOTAN_EXT_PIPE_UNIXFD_IO` is defined, then you can use the overloaded I/O operators with Unix file descriptors. For an example of this, check out the `hash_fd` example, included in the Botan distribution.

25.5 Filter Catalog

This section documents most of the useful filters included in the library.

25.5.1 Keyed Filters

A few sections ago, it was mentioned that `Pipe` can process multiple messages, treating each of them the same. Well, that was a bit of a lie. There are some algorithms (in particular, block ciphers not in ECB mode, and all stream ciphers) that change their state as data is put through them.

Naturally, you might well want to reset the keys or (in the case of block cipher modes) IVs used by such filters, so multiple messages can be processed using completely different keys, or new IVs, or new keys and IVs, or whatever. And in fact, even for a MAC or an ECB block cipher, you might well want to change the key used from message to message.

Enter `Keyed_Filter`, which acts as an abstract interface for any filter that is uses keys: block cipher modes, stream ciphers, MACs, and so on. It has two functions, `set_key` and `set_iv`. Calling `set_key` will set (or reset) the key used by the algorithm. Setting the IV only makes sense in certain algorithms – a call to `set_iv` on an object that doesn't support IVs will cause an exception. You must call `set_key` *before* calling `set_iv`.

Here's a example:

```
Keyed_Filter *aes, *hmac;
Pipe pipe(new Base64_Decoder,
          // Note the assignments to the cast and hmac variables
          aes = get_cipher("AES-128/CBC", aes_key, iv),
          new Fork(
             0, // Read the section 'Fork' to understand this
             new Chain(
                hmac = new MAC_Filter("HMAC(SHA-1)", mac_key, 12),
                new Base64_Encoder
                )
             )
   );
pipe.start_msg();
// use pipe for a while, decrypt some stuff, derive new keys and IVs
pipe.end_msg();

aes->set_key(aes_key2);
aes->set_iv(iv2);
hmac->set_key(mac_key2);

pipe.start_msg();
// use pipe for some other things
pipe.end_msg();
```

There are some requirements to using `Keyed_Filter` that you must follow. If you call `set_key` or `set_iv` on a filter that is owned by a `Pipe`, you must do so while the `Pipe` is "unlocked". This refers to the times when no messages are being processed by `Pipe` – either before `Pipe`'s `start_msg` is called, or after `end_msg` is called (and no new call to `start_msg` has happened yet). Doing otherwise will result in undefined behavior, probably silently getting invalid output.

And remember: if you're resetting both values, reset the key *first*.

25.5.2 Cipher Filters

Getting a hold of a `Filter` implementing a cipher is very easy. Make sure you're including the header `lookup.h`, and then call `get_cipher`. You will pass the return value directly into a `Pipe`. There are a couple different functions which do varying levels of initialization:

Keyed_Filter ***get_cipher**(std::string *cipher_spec*, SymmetricKey *key*, InitializationVector *iv*, Cipher_Dir *dir*)

Keyed_Filter ***get_cipher**(std::string *cipher_spec*, SymmetricKey *key*, Cipher_Dir *dir*)

The version that doesn't take an IV is useful for things that don't use them, like block ciphers in ECB mode, or most stream ciphers. If you specify a cipher spec that does want a IV, and you use the version that doesn't take one, an exception will be thrown. The `dir` argument can be either `ENCRYPTION` or `DECRYPTION`.

The cipher_spec is a string that specifies what cipher is to be used. The general syntax for "cipher_spec" is "STREAM_CIPHER", "BLOCK_CIPHER/MODE", or "BLOCK_CIPHER/MODE/PADDING". In the case of stream ciphers, no mode is necessary, so just the name is sufficient. A block cipher requires a mode of some sort, which can be "ECB", "CBC", "CFB(n)", "OFB", "CTR-BE", or "EAX(n)". The argument to CFB mode is how many bits of feedback should be used. If you just use "CFB" with no argument, it will default to using a feedback equal to the block size of the cipher. EAX mode also takes an optional bit argument, which tells EAX how large a tag size to use~–~generally this is the size of the block size of the cipher, which is the default if you don't specify any argument.

In the case of the ECB and CBC modes, a padding method can also be specified. If it is not supplied, ECB defaults to not padding, and CBC defaults to using PKCS #5/#7 compatible padding. The padding methods currently available are "NoPadding", "PKCS7", "OneAndZeros", and "CTS". CTS padding is currently only available for CBC mode, but the others can also be used in ECB mode.

Some example "cipher_spec arguments are: "AES-128/CBC", "Blowfish/CTR-BE", "Serpent/XTS", and "AES-256/EAX".

"CTR-BE" refers to counter mode where the counter is incremented as if it were a big-endian encoded integer. This is compatible with most other implementations, but it is possible some will use the incompatible little endian convention. This version would be denoted as "CTR-LE" if it were supported.

"EAX" is a new cipher mode designed by Wagner, Rogaway, and Bellare. It is an authenticated cipher mode (that is, no separate authentication is needed), has provable security, and is free from patent entanglements. It runs about half as fast as most of the other cipher modes (like CBC, OFB, or CTR), which is not bad considering you don't need to use an authentication code.

25.5.3 Hashes and MACs

Hash functions and MACs don't need anything special when it comes to filters. Both just take their input and produce no output until `end_msg` is called, at which time they complete the hash or MAC and send that as output.

These filters take a string naming the type to be used. If for some reason you name something that doesn't exist, an exception will be thrown.

Hash_Filter`::`**Hash_Filter**(std::string *hash*, size_t *outlen* = 0)

This constructor creates a filter that hashes its input with `hash`. When `end_msg` is called on the owning pipe, the hash is completed and the digest is sent on to the next filter in the pipeline. The parameter `outlen` specifies how many bytes of the hash output will be passed along to the next filter when `end_msg` is called. By default, it will pass the entire hash.

Examples of names for `Hash_Filter` are "SHA-1" and "Whirlpool".

MAC_Filter`::`**MAC_Filter**(std::string *mac*, SymmetricKey *key*, size_t *outlen* = 0)

This constructor takes a name for a mac, such as "HMAC(SHA-1)" or "CMAC(AES-128)", along with a key to use. The optional `outlen` works the same as in `Hash_Filter`.

25.5.4 Encoders

Often you want your data to be in some form of text (for sending over channels that aren't 8-bit clean, printing it, etc). The filters `Hex_Encoder` and `Base64_Encoder` will convert arbitrary binary data into hex or base64 formats. Not surprisingly, you can use `Hex_Decoder` and `Base64_Decoder` to convert it back into its original form.

Both of the encoders can take a few options about how the data should be formatted (all of which have defaults). The first is a `bool` which says if the encoder should insert line breaks. This defaults to false. Line breaks don't matter either way to the decoder, but it makes the output a bit more appealing to the human eye, and a few transport mechanisms (notably some email systems) limit the maximum line length.

The second encoder option is an integer specifying how long such lines will be (obviously this will be ignored if line-breaking isn't being used). The default tends to be in the range of 60-80 characters, but is not specified. If you want a specific value, set it. Otherwise the default should be fine.

Lastly, `Hex_Encoder` takes an argument of type `Case`, which can be `Uppercase` or `Lowercase` (default is `Uppercase`). This specifies what case the characters A-F should be output as. The base64 encoder has no such option, because it uses both upper and lower case letters for its output.

You can find the declarations for these types in `hex_filt.h` and `b64_filt.h`.

25.6 Writing New Filters

The system of filters and pipes was designed in an attempt to make it as simple as possible to write new filter types. There are four functions that need to be implemented by a class deriving from `Filter`:

void `Filter::write`(**const** uint8_t **input*, size_t *length*)
: This function is what is called when a filter receives input for it to process. The filter is not required to process the data right away; many filters buffer their input before producing any output. A filter will usually have `write` called many times during its lifetime.

void `Filter::send`(uint8_t **output*, size_t *length*)
: Eventually, a filter will want to produce some output to send along to the next filter in the pipeline. It does so by calling `send` with whatever it wants to send along to the next filter. There is also a version of `send` taking a single byte argument, as a convenience.

void `Filter::start_msg`()
: Implementing this function is optional. Implement it if your filter would like to do some processing or setup at the start of each message, such as allocating a data structure.

void `Filter::end_msg`()
: Implementing this function is optional. It is called when it has been requested that filters finish up their computations. The filter should finish up with whatever computation it is working on (for example, a compressing filter would flush the compressor and `send` the final block), and empty any buffers in preparation for processing a fresh new set of input.

Additionally, if necessary, filters can define a constructor that takes any needed arguments, and a destructor to deal with deallocating memory, closing files, etc.

CHAPTER

TWENTYSIX

FORMAT PRESERVING ENCRYPTION

Format preserving encryption (FPE) refers to a set of techniques for encrypting data such that the ciphertext has the same format as the plaintext. For instance, you can use FPE to encrypt credit card numbers with valid checksums such that the ciphertext is also an credit card number with a valid checksum, or similarly for bank account numbers, US Social Security numbers, or even more general mappings like English words onto other English words.

The scheme currently implemented in botan is called FE1, and described in the paper Format Preserving Encryption (https://eprint.iacr.org/2009/251) by Mihir Bellare, Thomas Ristenpart, Phillip Rogaway, and Till Stegers. FPE is an area of ongoing standardization and it is likely that other schemes will be included in the future.

To encrypt an arbitrary value using FE1, you need to use a ranking method. Basically, the idea is to assign an integer to every value you might encrypt. For instance, a 16 digit credit card number consists of a 15 digit code plus a 1 digit checksum. So to encrypt a credit card number, you first remove the checksum, encrypt the 15 digit value modulo 10^{15}, and then calculate what the checksum is for the new (ciphertext) number. Or, if you were encrypting words in a dictionary, you could rank the words by their lexicographical order, and choose the modulus to be the number of words in the dictionary.

The interfaces for FE1 are defined in the header `fpe_fe1.h`:

New in version 2.5.0.

class FPE_FE1

FPE_FE1(**const** *BigInt* &*n*, size_t *rounds* = 5, bool *compat_mode* = false, std::string *mac_algo* = "HMAC(SHA-256)")

Initialize an FPE operation to encrypt/decrypt integers less than *n*. It is expected that *n* is trivially factorable into small integers. Common usage would be n to be a power of 10.

Note that the default parameters to this constructor are **incompatible** with the `fe1_encrypt` and `fe1_decrypt` function originally added in 1.9.17. For compatibility, use 3 rounds and set `compat_mode` to true.

BigInt **encrypt**(**const** *BigInt* &*x*, **const** uint8_t *tweak*[], size_t *tweak_len*) **const**

Encrypts the value *x* modulo the value *n* using the *key* and *tweak* specified. Returns an integer less than *n*. The *tweak* is a value that does not need to be secret that parameterizes the encryption function. For instance, if you were encrypting a database column with a single key, you could use a per-row-unique integer index value as the tweak. The same tweak value must be used during decryption.

BigInt **decrypt**(**const** *BigInt* &*x*, **const** uint8_t *tweak*[], size_t *tweak_len*) **const**

Decrypts an FE1 ciphertext. The *tweak* must be the same as that provided to the encryption function. Returns the plaintext integer.

Note that there is not any implicit authentication or checking of data in FE1, so if you provide an incorrect key or tweak the result is simply a random integer.

BigInt **encrypt**(**const** *BigInt* &*x*, uint64_t *tweak*)

Convenience version of encrypt taking an integer tweak.

BigInt **decrypt**(**const** *BigInt* &*x*, uint64_t *tweak*)
Convenience version of decrypt taking an integer tweak.

There are two functions that handle the entire FE1 encrypt/decrypt operation. These are the original interface to FE1, first added in 1.9.17. However because they do the entire setup cost for each operation, they are significantly slower than the class-based API presented above.

Warning: These functions are hardcoded to use 3 rounds, which may be insufficient depending on the chosen modulus.

BigInt FPE::**fe1_encrypt**(**const** *BigInt* &*n*, **const** *BigInt* &*X*, **const** SymmetricKey &*key*, **const** std::vector<uint8_t> &*tweak*)
This creates an FPE_FE1 object, sets the key, and encrypts *X* using the provided tweak.

BigInt FPE::**fe1_decrypt**(**const** *BigInt* &*n*, **const** *BigInt* &*X*, **const** SymmetricKey &*key*, **const** std::vector<uint8_t> &*tweak*)
This creates an FPE_FE1 object, sets the key, and decrypts *X* using the provided tweak.

This example encrypts a credit card number with a valid Luhn checksum (https://en.wikipedia.org/wiki/Luhn_algorithm) to another number with the same format, including a correct checksum.

CHAPTER

TWENTYSEVEN

ELLIPTIC CURVE OPERATIONS

In addition to high level operations for signatures, key agreement, and message encryption using elliptic curve cryptography, the library contains lower level interfaces for performing operations such as elliptic curve point multiplication.

Only curves over prime fields are supported.

Many of these functions take a workspace, either a vector of words or a vector of BigInts. These are used to minimize memory allocations during common operations.

Warning: You should only use these interfaces if you know what you are doing.

class EC_Group

EC_Group(**const** OID &*oid*)
Initialize an `EC_Group` using an OID referencing the curve parameters.

EC_Group(**const** std::string &*name*)
Initialize an `EC_Group` using a name or OID (for example "secp256r1", or "1.2.840.10045.3.1.7")

EC_Group(**const** *BigInt* &*p*, **const** *BigInt* &*a*, **const** *BigInt* &*b*, **const** *BigInt* &*base_x*, **const** *BigInt* &*base_y*, **const** *BigInt* &*order*, **const** *BigInt* &*cofactor*, **const** OID &*oid* = OID())
Initialize an elliptic curve group from the relevant parameters. This is used for example to create custom (application-specific) curves.

EC_Group(**const** std::vector<uint8_t> &*ber_encoding*)
Initialize an `EC_Group` by decoding a DER encoded parameter block.

std::vector<uint8_t> **DER_encode**(EC_Group_Encoding *form*) **const**
Return the DER encoding of this group.

std::string **PEM_encode**() **const**
Return the PEM encoding of this group (base64 of DER encoding plus header/trailer).

bool **a_is_minus_3**() **const**
Return true if the `a` parameter is congruent to -3 mod p.

bool **a_is_zero**() **const**
Return true if the `a` parameter is congruent to 0 mod p.

size_t **get_p_bits**() **const**
Return size of the prime in bits.

size_t **get_p_bytes**() **const**
Return size of the prime in bytes.

size_t **get_order_bits**() **const**
Return size of the group order in bits.

size_t **get_order_bytes**() **const**
Return size of the group order in bytes.

const *BigInt* &**get_p**() **const**
Return the prime modulus.

const *BigInt* &**get_a**() **const**
Return the a parameter of the elliptic curve equation.

const *BigInt* &**get_b**() **const**
Return the b parameter of the elliptic curve equation.

const *PointGFp* &**get_base_point**() **const**
Return the groups base point element.

const *BigInt* &**get_g_x**() **const**
Return the x coordinate of the base point element.

const *BigInt* &**get_g_y**() **const**
Return the y coordinate of the base point element.

const *BigInt* &**get_order**() **const**
Return the order of the group generated by the base point.

const *BigInt* &**get_cofactor**() **const**
Return the cofactor of the curve. In most cases this will be 1.

BigInt **mod_order**(**const** *BigInt* &*x*) **const**
Reduce argument x modulo the curve order.

BigInt **inverse_mod_order**(**const** *BigInt* &*x*) **const**
Return inverse of argument x modulo the curve order.

BigInt **multiply_mod_order**(**const** *BigInt* &*x*, **const** *BigInt* &*y*) **const**
Multiply x and y and reduce the result modulo the curve order.

bool **verify_public_element**(**const** *PointGFp* &*y*) **const**
Return true if y seems to be a valid group element.

const OID &**get_curve_oid**() **const**
Return the OID used to identify the curve. May be empty.

PointGFp **point**(**const** *BigInt* &*x*, **const** *BigInt* &*y*) **const**
Create and return a point with affine elements x and y. Note this function *does not* verify that x and y satisfy the curve equation.

PointGFp **point_multiply**(**const** *BigInt* &*x*, **const** *PointGFp* &*pt*, **const** *BigInt* &*y*) **const**
Multi-exponentiation. Returns base_point*x + pt*y. Not constant time. (Ordinarily used for signature verification.)

PointGFp **blinded_base_point_multiply**(**const** *BigInt* &*k*, *RandomNumberGenerator* &*rng*, std::vector<*BigInt*> &*ws*) **const**
Return base_point*k in a way that attempts to resist side channels.

BigInt **blinded_base_point_multiply_x**(**const** *BigInt* &*k*, *RandomNumberGenerator* &*rng*, std::vector<*BigInt*> &*ws*) **const**
Like *blinded_base_point_multiply* but returns only the x coordinate.

PointGFp **blinded_var_point_multiply**(**const** *PointGFp* &*point*, **const** *BigInt* &*k*, *RandomNumberGenerator* &*rng*, std::vector<*BigInt*> &*ws*) **const**
Return `point*k` in a way that attempts to resist side channels.

BigInt **random_scalar**(*RandomNumberGenerator* &*rng*) **const**
Return a random scalar (ie an integer between 1 and the group order).

PointGFp **zero_point**() **const**
Return the zero point (aka the point at infinity).

PointGFp **OS2ECP**(**const** uint8_t *bits*[], size_t *len*) **const**
Decode a point from the binary encoding. This function verifies that the decoded point is a valid element on the curve.

bool **verify_group**(*RandomNumberGenerator* &*rng*, bool *strong* = false) **const**
Attempt to verify the group seems valid.

static const std::set<std::string> &**known_named_groups**()
Return a list of known groups, ie groups for which `EC_Group(name)` will succeed.

class PointGFp
Stores elliptic curve points in Jacobian representation.

std::vector<uint8_t> **encode**(*PointGFp*::Compression_Type *format*) **const**
Encode a point in a way that can later be decoded with *EC_Group::OS2ECP*.

PointGFp &**operator+=**(**const** *PointGFp* &*rhs*)
Point addition.

PointGFp &**operator-=**(**const** *PointGFp* &*rhs*)
Point subtraction.

PointGFp &**operator*=**(**const** *BigInt* &*scalar*)
Point multiplication using Montgomery ladder.

> **Warning:** Prefer the blinded functions in `EC_Group`

PointGFp &**negate**()
Negate this point.

BigInt **get_affine_x**() **const**
Return the affine `x` coordinate of the point.

BigInt **get_affine_y**() **const**
Return the affine `y` coordinate of the point.

void **force_affine**()
Convert the point to its equivalent affine coordinates. Throws if this is the point at infinity.

static void **force_all_affine**(std::vector<*PointGFp*> &*points*, secure_vector<word> &*ws*)
Force several points to be affine at once. Uses Montgomery's trick to reduce number of inversions required, so this is much faster than calling `force_affine` on each point in sequence.

bool **is_affine**() **const**
Return true if this point is in affine coordinates.

bool **is_zero**() **const**
Return true if this point is zero (aka point at infinity).

bool **on_the_curve**() **const**
Return true if this point is on the curve.

void **randomize_repr**(*RandomNumberGenerator* &*rng*)
Randomize the point representation.

bool **operator==**(**const** *PointGFp* &*other*) **const**
Point equality. This compares the affine representations.

void **add**(**const** *PointGFp* &*other*, std::vector<*BigInt*> &*workspace*)
Point addition, taking a workspace.

void **add_affine**(**const** *PointGFp* &*other*, std::vector<*BigInt*> &*workspace*)
Mixed (Jacobian+affine) addition, taking a workspace.

> **Warning:** This function assumes that `other` is affine, if this is not correct the result will be invalid.

void **mult2**(std::vector<*BigInt*> &*workspace*)
Point doubling.

void **mult2i**(size_t *i*, std::vector<*BigInt*> &*workspace*)
Repeated point doubling.

PointGFp **plus**(**const** *PointGFp* &*other*, std::vector<*BigInt*> &*workspace*) **const**
Point addition, returning the result.

PointGFp **double_of**(std::vector<*BigInt*> &*workspace*) **const**
Point doubling, returning the result.

PointGFp **zero**() **const**
Return the point at infinity

CHAPTER

TWENTYEIGHT

LOSSLESS DATA COMPRESSION

Some lossless data compression algorithms are available in botan, currently all via third party libraries - these include zlib (including deflate and gzip formats), bzip2, and lzma. Support for these must be enabled at build time; you can check for them using the macros `BOTAN_HAS_ZLIB`, `BOTAN_HAS_BZIP2`, and `BOTAN_HAS_LZMA`.

Note: You should always compress *before* you encrypt, because encryption seeks to hide the redundancy that compression is supposed to try to find and remove.

Compression is done through the `Compression_Algorithm` and `Decompression_Algorithm` classes, both defined in *compression.h*

Compression and decompression both work in three stages: starting a message (`start`), continuing to process it (`update`), and then finally completing processing the stream (`finish`).

class Compression_Algorithm

void **start**(size_t *level*)
: Initialize the compression engine. This must be done before calling `update` or `finish`. The meaning of the *level* parameter varies by the algorithm but generally takes a value between 1 and 9, with higher values implying typically better compression from and more memory and/or CPU time consumed by the compression process. The decompressor can always handle input from any compressor.

void **update**(secure_vector<uint8_t> &*buf*, size_t *offset* = 0, bool *flush* = false)

> Compress the material in the in/out parameter `buf`. The leading `offset` bytes of `buf` are ignored and remain untouched; this can be useful for ignoring packet headers. If `flush` is true, the compression state is flushed, allowing the decompressor to recover the entire message up to this point without having the see the rest of the compressed stream.

class Decompression_Algorithm

void **start**()
: Initialize the decompression engine. This must be done before calling `update` or `finish`. No level is provided here; the decompressor can accept input generated by any compression parameters.

void **update**(secure_vector<uint8_t> &*buf*, size_t *offset* = 0)

> Decompress the material in the in/out parameter `buf`. The leading `offset` bytes of `buf` are ignored and remain untouched; this can be useful for ignoring packet headers.
>
> This function may throw if the data seems to be invalid.

The easiest way to get a compressor is via the functions

Compression_Algorithm ***make_compressor**(std::string *type*)

Decompression_Algorithm ***make_decompressor**(std::string *type*)

Supported values for *type* include *zlib* (raw zlib with no checksum), *deflate* (zlib's deflate format), *gzip*, *bz2*, and *lzma*. A null pointer will be returned if the algorithm is unavailable.

To use a compression algorithm in a *Pipe* use the adapter types *Compression_Filter* and *Decompression_Filter* from *comp_filter.h*. The constructors of both filters take a *std::string* argument (passed to *make_compressor* or *make_decompressor*), the compression filter also takes a *level* parameter. Finally both constructors have a parameter *buf_sz* which specifies the size of the internal buffer that will be used - inputs will be broken into blocks of this size. The default is 4096.

CHAPTER

TWENTYNINE

PKCS#11

New in version 1.11.31.

PKCS#11 is a platform-independent interface for accessing smart cards and hardware security modules (HSM). Vendors of PKCS#11 compatible devices usually provide a so called middleware or "PKCS#11 module" which implements the PKCS#11 standard. This middleware translates calls from the platform-independent PKCS#11 API to device specific calls. So application developers don't have to write smart card or HSM specific code for each device they want to support.

Note: The Botan PKCS#11 interface is implemented against version v2.40 of the standard.

Botan wraps the C PKCS#11 API to provide a C++ PKCS#11 interface. This is done in two levels of abstraction: a low level API (see *Low Level API*) and a high level API (see *High Level API*). The low level API provides access to all functions that are specified by the standard. The high level API represents an object oriented approach to use PKCS#11 compatible devices but only provides a subset of the functions described in the standard.

To use the PKCS#11 implementation the `pkcs11` module has to be enabled.

Note: Both PKCS#11 APIs live in the namespace `Botan::PKCS11`

29.1 Low Level API

The PKCS#11 standards committee provides header files (`pkcs11.h`, `pkcs11f.h` and `pkcs11t.h`) which define the PKCS#11 API in the C programming language. These header files could be used directly to access PKCS#11 compatible smart cards or HSMs. The external header files are shipped with Botan in version v2.4 of the standard. The PKCS#11 low level API wraps the original PKCS#11 API, but still allows to access all functions described in the standard and has the advantage that it is a C++ interface with features like RAII, exceptions and automatic memory management.

The low level API is implemented by the *LowLevel* class and can be accessed by including the header `botan/p11.h`.

29.1.1 Preface

All constants that belong together in the PKCS#11 standard are grouped into C++ enum classes. For example the different user types are grouped in the *UserType* enumeration:

enum class UserType : CK_USER_TYPE

enumerator UserType::**SO** = CKU_SO

enumerator UserType::**User** = CKU_USER

enumerator UserType::**ContextSpecific** = CKU_CONTEXT_SPECIFIC

Additionally, all types that are used by the low or high level API are mapped by type aliases to more C++ like names. For instance:

using FunctionListPtr = CK_FUNCTION_LIST_PTR

C-API Wrapping

There is at least one method in the *LowLevel* class that corresponds to a PKCS#11 function. For example the *C_GetSlotList* method in the *LowLevel* class is defined as follows:

class LowLevel

bool **C_GetSlotList**(Bbool *token_present*, SlotId **slot_list_ptr*, Ulong **count_ptr*, *ReturnValue* **return_value* = ThrowException) **const**

The *LowLevel* class calls the PKCS#11 function from the function list of the PKCS#11 module:

```
CK_DEFINE_FUNCTION(CK_RV, C_GetSlotList)( CK_BBOOL tokenPresent, CK_SLOT_ID_
↪PTR pSlotList,
                                          CK_ULONG_PTR pulCount )
```

Where it makes sense there is also an overload of the *LowLevel* method to make usage easier and safer:

bool **C_GetSlotList**(bool *token_present*, std::vector<SlotId> &*slot_ids*, *ReturnValue* **return_value* = ThrowException) **const**

With this overload the user of this API just has to pass a vector of `SlotId` instead of pointers to preallocated memory for the slot list and the number of elements. Additionally, there is no need to call the method twice in order to determine the number of elements first.

Another example is the *C_InitPIN* overload:

template<typename **Talloc**>
bool **C_InitPIN**(SessionHandle *session*, **const** std::vector<uint8_t, TAlloc> &*pin*, *ReturnValue* **return_value* = ThrowException) **const**

The templated `pin` parameter allows to pass the PIN as a `std::vector<uint8_t>` or a `secure_vector<uint8_t>`. If used with a `secure_vector` it is assured that the memory is securely erased when the `pin` object is no longer needed.

Error Handling

All possible PKCS#11 return values are represented by the enum class:

enum class ReturnValue : CK_RV

All methods of the *LowLevel* class have a default parameter `ReturnValue* return_value = ThrowException`. This parameter controls the error handling of all *LowLevel* methods. The default behavior `return_value = ThrowException` is to throw an exception if the method does not complete successfully. If a non-`NULL` pointer is passed, `return_value` receives the return value of the PKCS#11 function and no exception is thrown. In case `nullptr` is passed as `return_value`, the exact return value is ignored and the method just returns `true` if the function succeeds and `false` otherwise.

29.1.2 Getting started

An object of this class can be instantiated by providing a *FunctionListPtr* to the *LowLevel* constructor:

explicit LowLevel (*FunctionListPtr ptr*)

The *LowLevel* class provides a static method to retrieve a *FunctionListPtr* from a PKCS#11 module file:

static bool **C_GetFunctionList** (Dynamically_Loaded_Library *&pkcs11_module*, *FunctionListPtr *function_list_ptr_ptr*, *ReturnValue *return_value* = ThrowException)

Code Example: Object Instantiation

```
Botan::Dynamically_Loaded_Library pkcs11_module( "C:\\pkcs11-
↪middleware\\library.dll" );
Botan::PKCS11::FunctionListPtr func_list = nullptr;
Botan::PKCS11::LowLevel::C_GetFunctionList( pkcs11_module, &func_list );
Botan::PKCS11::LowLevel p11_low_level( func_list );
```

Code Example: PKCS#11 Module Initialization

```
Botan::PKCS11::LowLevel p11_low_level(func_list);

Botan::PKCS11::C_InitializeArgs init_args = { nullptr, nullptr, nullptr,␣
↪nullptr,
        static_cast<CK_FLAGS>(Botan::PKCS11::Flag::OsLockingOk), nullptr };

p11_low_level.C_Initialize(&init_args);

// work with the token

p11_low_level.C_Finalize(nullptr);
```

More code examples can be found in the test suite in the `test_pkcs11_low_level.cpp` file.

29.2 High Level API

The high level API provides access to the most commonly used PKCS#11 functionality in an object oriented manner. Functionality of the high level API includes:

- Loading/unloading of PKCS#11 modules
- Initialization of tokens
- Change of PIN/SO-PIN

- Session management
- Random number generation
- Enumeration of objects on the token (certificates, public keys, private keys)
- Import/export/deletion of certificates
- Generation/import/export/deletion of RSA and EC public and private keys
- Encryption/decryption using RSA with support for OAEP and PKCS1-v1_5 (and raw)
- Signature generation/verification using RSA with support for PSS and PKCS1-v1_5 (and raw)
- Signature generation/verification using ECDSA
- Key derivation using ECDH

29.2.1 Module

The *Module* class represents a PKCS#11 shared library (module) and is defined in `botan/p11_module.h`.

It is constructed from a a file path to a PKCS#11 module and optional `C_InitializeArgs`:

class Module

```
Module(const std::string& file_path, C_InitializeArgs init_args =
   { nullptr, nullptr, nullptr, nullptr, static_cast<CK_FLAGS>(Flag::OsLockingOk),
↪ nullptr })
```

It loads the shared library and calls `C_Initialize` with the provided `C_InitializeArgs`. On destruction of the object `C_Finalize` is called.

There are two more methods in this class. One is for reloading the shared library and reinitializing the PKCS#11 module:

```
void reload(C_InitializeArgs init_args =
   { nullptr, nullptr, nullptr, nullptr, static_cast< CK_FLAGS >
↪(Flag::OsLockingOk), nullptr });
```

The other one is for getting general information about the PKCS#11 module:

Info **get_info**() **const**
: This function calls `C_GetInfo` internally.

Code example:

```
Botan::PKCS11::Module module( "C:\\pkcs11-middleware\\library.dll" );

// Sometimes useful if a newly connected token is not detected by the PKCS
↪#11 module
module.reload();

Botan::PKCS11::Info info = module.get_info();

// print library version
std::cout << std::to_string( info.libraryVersion.major ) << "."
   << std::to_string( info.libraryVersion.minor ) << std::endl;
```

29.2.2 Slot

The *Slot* class represents a PKCS#11 slot and is defined in `botan/p11_slot.h`.

A PKCS#11 slot is usually a smart card reader that potentially contains a token.

class Slot

Slot (*Module* &*module*, SlotId *slot_id*)
To instantiate this class a reference to a *Module* object and a `slot_id` have to be passed to the constructor.

static std::vector<SlotId> **get_available_slots** (*Module* &*module*, bool *token_present*)
Retrieve available slot ids by calling this static method.

The parameter `token_present` controls whether all slots or only slots with a token attached are returned by this method. This method calls *C_GetSlotList*.

SlotInfo **get_slot_info** () **const**
Returns information about the slot. Calls `C_GetSlotInfo`.

TokenInfo **get_token_info** () **const**
Obtains information about a particular token in the system. Calls `C_GetTokenInfo`.

std::vector<MechanismType> **get_mechanism_list** () **const**
Obtains a list of mechanism types supported by the slot. Calls `C_GetMechanismList`.

MechanismInfo **get_mechanism_info** (MechanismType *mechanism_type*) **const**
Obtains information about a particular mechanism possibly supported by a slot. Calls `C_GetMechanismInfo`.

void **initialize** (**const** std::string &*label*, **const** secure_string &*so_pin*) **const**
Calls `C_InitToken` to initialize the token. The `label` must not exceed 32 bytes. The current PIN of the security officer must be passed in `so_pin` if the token is reinitialized or if it's a factory new token, the `so_pin` that is passed will initially be set.

Code example:

```
// only slots with connected token
std::vector<Botan::PKCS11::SlotId> slots = Botan::PKCS11::Slot::get_
↪available_slots( module, true );

// use first slot
Botan::PKCS11::Slot slot( module, slots.at( 0 ) );

// print firmware version of the slot
Botan::PKCS11::SlotInfo slot_info = slot.get_slot_info();
std::cout << std::to_string( slot_info.firmwareVersion.major ) << "."
   << std::to_string( slot_info.firmwareVersion.minor ) << std::endl;

// print firmware version of the token
Botan::PKCS11::TokenInfo token_info = slot.get_token_info();
std::cout << std::to_string( token_info.firmwareVersion.major ) << "."
   << std::to_string( token_info.firmwareVersion.minor ) << std::endl;

// retrieve all mechanisms supported by the token
std::vector<Botan::PKCS11::MechanismType> mechanisms = slot.get_mechanism_
↪list();
```

(continues on next page)

(continued from previous page)

```
// retrieve information about a particular mechanism
Botan::PKCS11::MechanismInfo mech_info =
   slot.get_mechanism_info( Botan::PKCS11::MechanismType::RsaPkcsOaep );

// maximum RSA key length supported:
std::cout << mech_info.ulMaxKeySize << std::endl;

// initialize the token
Botan::PKCS11::secure_string so_pin( 8, '0' );
slot.initialize( "Botan PKCS11 documentation test label", so_pin );
```

29.2.3 Session

The *Session* class represents a PKCS#11 session and is defined in `botan/p11_session.h`.

A session is a logical connection between an application and a token.

class Session

There are two constructors to create a new session and one constructor to take ownership of an existing session. The destructor calls `C_Logout` if a user is logged in to this session and always `C_CloseSession`.

Session (*Slot* &*slot*, bool *read_only*)
: To initialize a session object a *Slot* has to be specified on which the session should operate. `read_only` specifies whether the session should be read only or read write. Calls `C_OpenSession`.

Session (*Slot* &*slot*, Flags *flags*, VoidPtr *callback_data*, Notify *notify_callback*)
: Creates a new session by passing a *Slot*, session `flags`, `callback_data` and a `notify_callback`. Calls `C_OpenSession`.

Session (*Slot* &*slot*, SessionHandle *handle*)
: Takes ownership of an existing session by passing *Slot* and a session `handle`.

SessionHandle **release** ()
: Returns the released `SessionHandle`

void **login** (*UserType userType*, **const** secure_string &*pin*)
: Login to this session by passing *UserType* and `pin`. Calls `C_Login`.

void **logoff** ()
: Logout from this session. Not mandatory because on destruction of the *Session* object this is done automatically.

SessionInfo **get_info** () **const**
: Returns information about this session. Calls `C_GetSessionInfo`.

void **set_pin** (**const** secure_string &*old_pin*, **const** secure_string &*new_pin*) **const**
: Calls `C_SetPIN` to change the PIN of the logged in user using the `old_pin`.

void **init_pin** (**const** secure_string &*new_pin*)
: Calls *C_InitPIN* to change or initialize the PIN using the SO_PIN (requires a logged in session).

Code example:

```
// open read only session
{
Botan::PKCS11::Session read_only_session( slot, true );
}

// open read write session
{
Botan::PKCS11::Session read_write_session( slot, false );
}

// open read write session by passing flags
{
Botan::PKCS11::Flags flags =
   Botan::PKCS11::flags( Botan::PKCS11::Flag::SerialSession |␣
↪Botan::PKCS11::Flag::RwSession );

Botan::PKCS11::Session read_write_session( slot, flags, nullptr, nullptr );
}

// move ownership of a session
{
Botan::PKCS11::Session session( slot, false );
Botan::PKCS11::SessionHandle handle = session.release();

Botan::PKCS11::Session session2( slot, handle );
}

Botan::PKCS11::Session session( slot, false );

// get session info
Botan::PKCS11::SessionInfo info = session.get_info();
std::cout << info.slotID << std::endl;

// login
Botan::PKCS11::secure_string pin = { '1', '2', '3', '4', '5', '6' };
session.login( Botan::PKCS11::UserType::User, pin );

// set pin
Botan::PKCS11::secure_string new_pin = { '6', '5', '4', '3', '2', '1' };
session.set_pin( pin, new_pin );

// logoff
session.logoff();

// log in as security officer
Botan::PKCS11::secure_string so_pin = { '0', '0', '0', '0', '0', '0', '0', '0
↪' };
session.login( Botan::PKCS11::UserType::SO, so_pin );

// change pin to old pin
session.init_pin( pin );
```

29.2.4 Objects

PKCS#11 objects consist of various attributes (`CK_ATTRIBUTE`). For example `CKA_TOKEN` describes if a PKCS#11 object is a session object or a token object. The helper class *`AttributeContainer`* helps with storing these

attributes. The class is defined in `botan/p11_object.h`.

class AttributeContainer

Attributes can be set in an *AttributeContainer* by various `add_` methods:

void **add_class**(ObjectClass *object_class*)
Add a class attribute (`CKA_CLASS` / `AttributeType::Class`)

void **add_string**(AttributeType *attribute*, **const** std::string &*value*)
Add a string attribute (e.g. `CKA_LABEL` / `AttributeType::Label`).

void *AttributeContainer*`::`**add_binary**(AttributeType *attribute*, **const** uint8_t **value*, size_t *length*)
Add a binary attribute (e.g. `CKA_ID` / `AttributeType::Id`).

template<typename **TAlloc**>
void *AttributeContainer*`::`**add_binary**(AttributeType *attribute*, **const** std::vector<uint8_t, *TAlloc*> &*binary*)
Add a binary attribute by passing a `vector/secure_vector` (e.g. `CKA_ID` / `AttributeType::Id`).

void `AttributeContainer::`**add_bool**(AttributeType *attribute*, bool *value*)

Add a bool attribute (e.g. `CKA_SENSITIVE` / `AttributeType::Sensitive`).

template<typename **T**>
void `AttributeContainer::`**add_numeric**(AttributeType *attribute*, *T value*)
Add a numeric attribute (e.g. `CKA_MODULUS_BITS` / `AttributeType::ModulusBits`).

Object Properties

The PKCS#11 standard defines the mandatory and optional attributes for each object class. The mandatory and optional attribute requirements are mapped in so called property classes. Mandatory attributes are set in the constructor, optional attributes can be set via `set_` methods.

In the top hierarchy is the *ObjectProperties* class which inherits from the *AttributeContainer*. This class represents the common attributes of all PKCS#11 objects.

class ObjectProperties : **public** *AttributeContainer*

The constructor is defined as follows:

ObjectProperties(ObjectClass *object_class*)
Every PKCS#11 object needs an object class attribute.

The next level defines the *StorageObjectProperties* class which inherits from *ObjectProperties*.

class StorageObjectProperties : **public** *ObjectProperties*

The only mandatory attribute is the object class, so the constructor is defined as follows:

StorageObjectProperties(ObjectClass *object_class*)

But in contrast to the *ObjectProperties* class there are various setter methods. For example to set the `AttributeType::Label`:

void **set_label**(**const** std::string &*label*)
Sets the label description of the object (RFC2279 string).

The remaining hierarchy is defined as follows:

- `DataObjectProperties` inherits from *StorageObjectProperties*

- `CertificateProperties` inherits from *`StorageObjectProperties`*
- `DomainParameterProperties` inherits from *`StorageObjectProperties`*
- `KeyProperties` inherits from *`StorageObjectProperties`*
- `PublicKeyProperties` inherits from `KeyProperties`
- `PrivateKeyProperties` inherits from `KeyProperties`
- `SecretKeyProperties` inherits from `KeyProperties`

PKCS#11 objects themselves are represented by the *`Object`* class.

class Object

Following constructors are defined:

Object(*Session* &*session*, ObjectHandle *handle*)
Takes ownership over an existing object.

Object(*Session* &*session*, **const** *ObjectProperties* &*obj_props*)
Creates a new object with the *`ObjectProperties`* provided in `obj_props`.

The other methods are:

secure_vector<uint8_t> **get_attribute_value**(AttributeType *attribute*) **const**
Returns the value of the given attribute (using `C_GetAttributeValue`)

void **set_attribute_value**(AttributeType *attribute*, **const** secure_vector<uint8_t> &*value*) **const**
Sets the given value for the attribute (using `C_SetAttributeValue`)

void **destroy**() **const**
Destroys the object.

ObjectHandle **copy**(**const** *AttributeContainer* &*modified_attributes*) **const**
Allows to copy the object with modified attributes.

And static methods to search for objects:

template<typename **T**>
static std::vector<*T*> **search**(*Session* &*session*, **const** std::vector<Attribute> &*search_template*)
Searches for all objects of the given type that match `search_template`.

template<typename **T**>
static std::vector<*T*> **search**(*Session* &*session*, **const** std::string &*label*)
Searches for all objects of the given type using the label (`CKA_LABEL`).

template<typename **T**>
static std::vector<*T*> **search**(*Session* &*session*, **const** std::vector<uint8_t> &*id*)
Searches for all objects of the given type using the id (`CKA_ID`).

template<typename **T**>
static std::vector<*T*> **search**(*Session* &*session*, **const** std::string &*label*, **const** std::vector<uint8_t> &*id*)
Searches for all objects of the given type using the label (`CKA_LABEL`) and id (`CKA_ID`).

template<typename **T**>
static std::vector<*T*> **search**(*Session* &*session*)
Searches for all objects of the given type.

The ObjectFinder

Another way for searching objects is to use the *ObjectFinder* class. This class manages calls to the C_FindObjects* functions: C_FindObjectsInit, C_FindObjects and C_FindObjectsFinal.

class ObjectFinder

The constructor has the following signature:

ObjectFinder(*Session* &*session*, **const** std::vector<Attribute> &*search_template*)
A search can be prepared with an ObjectSearcher by passing a *Session* and a search_template.

The actual search operation is started by calling the *find* method:

std::vector<ObjectHandle> **find**(std::uint32_t *max_count* = 100) **const**
Starts or continues a search for token and session objects that match a template. max_count specifies the maximum number of search results (object handles) that are returned.

void **finish**()
Finishes the search operation manually to allow a new *ObjectFinder* to exist. Otherwise the search is finished by the destructor.

Code example:

```
// create an simple data object
Botan::secure_vector<uint8_t> value = { 0x00, 0x01 ,0x02, 0x03 };
std::size_t id = 1337;
std::string label = "test data object";

// set properties of the new object
Botan::PKCS11::DataObjectProperties data_obj_props;
data_obj_props.set_label( label );
data_obj_props.set_value( value );
data_obj_props.set_token( true );
data_obj_props.set_modifiable( true );
data_obj_props.set_object_id( Botan::DER_Encoder().encode( id ).get_contents_
↪unlocked() );

// create the object
Botan::PKCS11::Object data_obj( session, data_obj_props );

// get label of this object
Botan::PKCS11::secure_string retrieved_label =
   data_obj.get_attribute_value( Botan::PKCS11::AttributeType::Label );

// set a new label
Botan::PKCS11::secure_string new_label = { 'B', 'o', 't', 'a', 'n' };
data_obj.set_attribute_value( Botan::PKCS11::AttributeType::Label, new_label␣
↪);

// copy the object
Botan::PKCS11::AttributeContainer copy_attributes;
copy_attributes.add_string( Botan::PKCS11::AttributeType::Label, "copied␣
↪object" );
Botan::PKCS11::ObjectHandle copied_obj_handle = data_obj.copy( copy_
↪attributes );
```

(continues on next page)

(continued from previous page)

```
// search for an object
Botan::PKCS11::AttributeContainer search_template;
search_template.add_string( Botan::PKCS11::AttributeType::Label, "Botan" );
auto found_objs =
   Botan::PKCS11::Object::search<Botan::PKCS11::Object>( session, search_
↪template.attributes() );

// destroy the object
data_obj.destroy();
```

29.2.5 RSA

PKCS#11 RSA support is implemented in `<botan/p11_rsa.h>`.

RSA Public Keys

PKCS#11 RSA public keys are provided by the class *PKCS11_RSA_PublicKey*. This class inherits from `RSA_PublicKey` and *Object*. Furthermore there are two property classes defined to generate and import RSA public keys analogous to the other property classes described before: `RSA_PublicKeyGenerationProperties` and `RSA_PublicKeyImportProperties`.

class PKCS11_RSA_PublicKey : **public** RSA_PublicKey, **public** *Object*

PKCS11_RSA_PublicKey(*Session* &*session*, ObjectHandle *handle*)
Existing PKCS#11 RSA public keys can be used by providing an `ObjectHandle` to the constructor.

PKCS11_RSA_PublicKey(*Session* &*session*, **const** RSA_PublicKeyImportProperties &*pubkey_props*)
This constructor can be used to import an existing RSA public key with the `RSA_PublicKeyImportProperties` passed in `pubkey_props` to the token.

RSA Private Keys

The support for PKCS#11 RSA private keys is implemented in a similar way. There are two property classes: `RSA_PrivateKeyGenerationProperties` and `RSA_PrivateKeyImportProperties`. The *PKCS11_RSA_PrivateKey* class implements the actual support for PKCS#11 RSA private keys. This class inherits from `Private_Key`, `RSA_PublicKey` and *Object*. In contrast to the public key class there is a third constructor to generate private keys directly on the token or in the session and one method to export private keys.

class PKCS11_RSA_PrivateKey : **public** Private_Key, **public** RSA_PublicKey, **public** *Object*

PKCS11_RSA_PrivateKey(*Session* &*session*, ObjectHandle *handle*)
Existing PKCS#11 RSA private keys can be used by providing an `ObjectHandle` to the constructor.

PKCS11_RSA_PrivateKey(*Session* &*session*, **const** RSA_PrivateKeyImportProperties &*priv_key_props*)
This constructor can be used to import an existing RSA private key with the `RSA_PrivateKeyImportProperties` passed in `priv_key_props` to the token.

PKCS11_RSA_PrivateKey(*Session &session*, uint32_t *bits*, **const** RSA_PrivateKeyGenerationProperties &*priv_key_props*)
Generates a new PKCS#11 RSA private key with bit length provided in `bits` and the `RSA_PrivateKeyGenerationProperties` passed in `priv_key_props`.

RSA_PrivateKey **export_key**() **const**
Returns the exported `RSA_PrivateKey`.

PKCS#11 RSA key pairs can be generated with the following free function:

PKCS11_RSA_KeyPair `PKCS11`**::generate_rsa_keypair**(*Session &session*, **const** RSA_PublicKeyGenerationProperties &*pub_props*, **const** RSA_PrivateKeyGenerationProperties &*priv_props*)

Code example:

```
Botan::PKCS11::secure_string pin = { '1', '2', '3', '4', '5', '6' };
session.login( Botan::PKCS11::UserType::User, pin );

/************ import RSA private key *************/

// create private key in software
Botan::AutoSeeded_RNG rng;
Botan::RSA_PrivateKey priv_key_sw( rng, 2048 );

// set the private key import properties
Botan::PKCS11::RSA_PrivateKeyImportProperties
   priv_import_props( priv_key_sw.get_n(), priv_key_sw.get_d() );

priv_import_props.set_pub_exponent( priv_key_sw.get_e() );
priv_import_props.set_prime_1( priv_key_sw.get_p() );
priv_import_props.set_prime_2( priv_key_sw.get_q() );
priv_import_props.set_coefficient( priv_key_sw.get_c() );
priv_import_props.set_exponent_1( priv_key_sw.get_d1() );
priv_import_props.set_exponent_2( priv_key_sw.get_d2() );

priv_import_props.set_token( true );
priv_import_props.set_private( true );
priv_import_props.set_decrypt( true );
priv_import_props.set_sign( true );

// import
Botan::PKCS11::PKCS11_RSA_PrivateKey priv_key( session, priv_import_props );

/************ export PKCS#11 RSA private key *************/
Botan::RSA_PrivateKey exported = priv_key.export_key();

/************ import RSA public key *************/

// set the public key import properties
Botan::PKCS11::RSA_PublicKeyImportProperties pub_import_props( priv_key.get_
↪n(), priv_key.get_e() );
pub_import_props.set_token( true );
pub_import_props.set_encrypt( true );
pub_import_props.set_private( false );
```

(continues on next page)

(continued from previous page)

```
// import
Botan::PKCS11::PKCS11_RSA_PublicKey public_key( session, pub_import_props );

/************ generate RSA private key *************/

Botan::PKCS11::RSA_PrivateKeyGenerationProperties priv_generate_props;
priv_generate_props.set_token( true );
priv_generate_props.set_private( true );
priv_generate_props.set_sign( true );
priv_generate_props.set_decrypt( true );

```

29.2.6 ECDSA

PKCS#11 ECDSA support is implemented in <botan/p11_ecdsa.h>.

ECDSA Public Keys

PKCS#11 ECDSA public keys are provided by the class *PKCS11_ECDSA_PublicKey*. This class inherits from PKCS11_EC_PublicKey and ECDSA_PublicKey. The necessary property classes are defined in <botan/p11_ecc_key.h>. For public keys there are EC_PublicKeyGenerationProperties and EC_PublicKeyImportProperties.

class PKCS11_ECDSA_PublicKey : **public** PKCS11_EC_PublicKey, **public virtual** ECDSA_PublicKey

PKCS11_ECDSA_PublicKey(*Session* &*session*, ObjectHandle *handle*)
Existing PKCS#11 ECDSA private keys can be used by providing an ObjectHandle to the constructor.

PKCS11_ECDSA_PublicKey(*Session* &*session*, **const** EC_PublicKeyImportProperties &*props*)
This constructor can be used to import an existing ECDSA public key with the EC_PublicKeyImportProperties passed in props to the token.

ECDSA_PublicKey *PKCS11_ECDSA_PublicKey*::**export_key**() **const**
Returns the exported ECDSA_PublicKey.

ECDSA Private Keys

The class *PKCS11_ECDSA_PrivateKey* inherits from PKCS11_EC_PrivateKey and implements support for PKCS#11 ECDSA private keys. There are two property classes for key generation and import: EC_PrivateKeyGenerationProperties and EC_PrivateKeyImportProperties.

class PKCS11_ECDSA_PrivateKey : **public** PKCS11_EC_PrivateKey

PKCS11_ECDSA_PrivateKey(*Session* &*session*, ObjectHandle *handle*)
Existing PKCS#11 ECDSA private keys can be used by providing an ObjectHandle to the constructor.

PKCS11_ECDSA_PrivateKey(*Session* &*session*, **const** EC_PrivateKeyImportProperties &*props*)
This constructor can be used to import an existing ECDSA private key with the EC_PrivateKeyImportProperties passed in props to the token.

PKCS11_ECDSA_PrivateKey(*Session* &*session*, **const** std::vector<uint8_t> &*ec_params*, **const** EC_PrivateKeyGenerationProperties &*props*)
This constructor can be used to generate a new ECDSA private key with the EC_PrivateKeyGenerationProperties passed in props on the token. The ec_params parameter is the DER-encoding of an ANSI X9.62 Parameters value.

ECDSA_PrivateKey **export_key**() **const**
Returns the exported ECDSA_PrivateKey.

PKCS#11 ECDSA key pairs can be generated with the following free function:

PKCS11_ECDSA_KeyPair PKCS11::**generate_ecdsa_keypair**(*Session* &*session*, **const** EC_PublicKeyGenerationProperties &*pub_props*, **const** EC_PrivateKeyGenerationProperties &*priv_props*)

Code example:

```
Botan::PKCS11::secure_string pin = { '1', '2', '3', '4', '5', '6' };
session.login( Botan::PKCS11::UserType::User, pin );

/************* import ECDSA private key *************/

// create private key in software
Botan::AutoSeeded_RNG rng;

Botan::ECDSA_PrivateKey priv_key_sw( rng, Botan::EC_Group( "secp256r1" ) );
priv_key_sw.set_parameter_encoding( Botan::EC_Group_Encoding::EC_DOMPAR_ENC_
↪OID );

// set the private key import properties
Botan::PKCS11::EC_PrivateKeyImportProperties priv_import_props(
   priv_key_sw.DER_domain(), priv_key_sw.private_value() );

priv_import_props.set_token( true );
priv_import_props.set_private( true );
priv_import_props.set_sign( true );
priv_import_props.set_extractable( true );

// label
std::string label = "test ECDSA key";
priv_import_props.set_label( label );

// import to card
Botan::PKCS11::PKCS11_ECDSA_PrivateKey priv_key( session, priv_import_props␣
↪);

/************* export PKCS#11 ECDSA private key *************/
Botan::ECDSA_PrivateKey priv_exported = priv_key.export_key();

/************* import ECDSA public key *************/

// import to card
Botan::PKCS11::EC_PublicKeyImportProperties pub_import_props( priv_key_sw.
↪DER_domain(),
   Botan::DER_Encoder().encode( EC2OSP( priv_key_sw.public_point(),␣
↪Botan::PointGFp::UNCOMPRESSED ),
   Botan::OCTET_STRING ).get_contents_unlocked() );

pub_import_props.set_token( true );
pub_import_props.set_verify( true );
pub_import_props.set_private( false );

// label
label = "test ECDSA pub key";
pub_import_props.set_label( label );

Botan::PKCS11::PKCS11_ECDSA_PublicKey public_key( session, pub_import_props␣
↪);

/************* export PKCS#11 ECDSA public key *************/
Botan::ECDSA_PublicKey pub_exported = public_key.export_key();
```

(continues on next page)

(continued from previous page)

```
/************* generate PKCS#11 ECDSA private key *************/
Botan::PKCS11::EC_PrivateKeyGenerationProperties priv_generate_props;
priv_generate_props.set_token( true );
priv_generate_props.set_private( true );
priv_generate_props.set_sign( true );

Botan::PKCS11::PKCS11_ECDSA_PrivateKey pk( session,
   Botan::EC_Group( "secp256r1" ).DER_encode( Botan::EC_Group_Encoding::EC_
↪DOMPAR_ENC_OID ),
   priv_generate_props );

/************* generate PKCS#11 ECDSA key pair *************/

Botan::PKCS11::EC_PublicKeyGenerationProperties pub_generate_props(
   Botan::EC_Group( "secp256r1" ).DER_encode(Botan::EC_Group_Encoding::EC_
↪DOMPAR_ENC_OID ) );

pub_generate_props.set_label( "BOTAN_TEST_ECDSA_PUB_KEY" );
pub_generate_props.set_token( true );
pub_generate_props.set_verify( true );
pub_generate_props.set_private( false );
pub_generate_props.set_modifiable( true );

Botan::PKCS11::PKCS11_ECDSA_KeyPair key_pair = Botan::PKCS11::generate_ecdsa_
↪keypair( session,
   pub_generate_props, priv_generate_props );

/************* PKCS#11 ECDSA sign and verify *************/

std::vector<uint8_t> plaintext( 20, 0x01 );

Botan::PK_Signer signer( key_pair.second, rng, "Raw", Botan::IEEE_1363,
↪"pkcs11" );
auto signature = signer.sign_message( plaintext, rng );

Botan::PK_Verifier token_verifier( key_pair.first, "Raw", Botan::IEEE_1363,
↪"pkcs11" );
bool ecdsa_ok = token_verifier.verify_message( plaintext, signature );
```

29.2.7 ECDH

PKCS#11 ECDH support is implemented in `<botan/p11_ecdh.h>`.

ECDH Public Keys

PKCS#11 ECDH public keys are provided by the class *PKCS11_ECDH_PublicKey*. This class inherits from `PKCS11_EC_PublicKey`. The necessary property classes are defined in `<botan/p11_ecc_key.h>`. For public keys there are `EC_PublicKeyGenerationProperties` and `EC_PublicKeyImportProperties`.

class PKCS11_ECDH_PublicKey : **public** PKCS11_EC_PublicKey

PKCS11_ECDH_PublicKey (*Session* &*session*, ObjectHandle *handle*)
Existing PKCS#11 ECDH private keys can be used by providing an `ObjectHandle` to the constructor.

PKCS11_ECDH_PublicKey(*Session* &*session*, **const** EC_PublicKeyImportProperties &*props*)
This constructor can be used to import an existing ECDH public key with the `EC_PublicKeyImportProperties` passed in `props` to the token.

ECDH_PublicKey **export_key**() **const**
Returns the exported `ECDH_PublicKey`.

ECDH Private Keys

The class *PKCS11_ECDH_PrivateKey* inherits from `PKCS11_EC_PrivateKey` and `PK_Key_Agreement_Key` and implements support for PKCS#11 ECDH private keys. There are two property classes. One for key generation and one for import: `EC_PrivateKeyGenerationProperties` and `EC_PrivateKeyImportProperties`.

class PKCS11_ECDH_PrivateKey : **public virtual** PKCS11_EC_PrivateKey, **public virtual** PK_Key_Agreement_K

PKCS11_ECDH_PrivateKey(*Session* &*session*, ObjectHandle *handle*)
Existing PKCS#11 ECDH private keys can be used by providing an `ObjectHandle` to the constructor.

PKCS11_ECDH_PrivateKey(*Session* &*session*, **const** EC_PrivateKeyImportProperties &*props*)
This constructor can be used to import an existing ECDH private key with the `EC_PrivateKeyImportProperties` passed in `props` to the token.

PKCS11_ECDH_PrivateKey(*Session* &*session*, **const** std::vector<uint8_t> &*ec_params*, **const** EC_PrivateKeyGenerationProperties &*props*)
This constructor can be used to generate a new ECDH private key with the `EC_PrivateKeyGenerationProperties` passed in `props` on the token. The `ec_params` parameter is the DER-encoding of an ANSI X9.62 Parameters value.

ECDH_PrivateKey **export_key**() **const**
Returns the exported `ECDH_PrivateKey`.

PKCS#11 ECDH key pairs can be generated with the following free function:

PKCS11_ECDH_KeyPair `PKCS11`**::generate_ecdh_keypair**(*Session* &*session*, **const** EC_PublicKeyGenerationProperties &*pub_props*, **const** EC_PrivateKeyGenerationProperties &*priv_props*)

Code example:

```
Botan::PKCS11::secure_string pin = { '1', '2', '3', '4', '5', '6' };
session.login( Botan::PKCS11::UserType::User, pin );

/************* import ECDH private key *************/

Botan::AutoSeeded_RNG rng;

// create private key in software
Botan::ECDH_PrivateKey priv_key_sw( rng, Botan::EC_Group( "secp256r1" ) );
priv_key_sw.set_parameter_encoding( Botan::EC_Group_Encoding::EC_DOMPAR_ENC_
↪OID );

// set import properties
```

(continues on next page)

(continued from previous page)

```
Botan::PKCS11::EC_PrivateKeyImportProperties priv_import_props(
   priv_key_sw.DER_domain(), priv_key_sw.private_value() );

priv_import_props.set_token( true );
priv_import_props.set_private( true );
priv_import_props.set_derive( true );
priv_import_props.set_extractable( true );

// label
std::string label = "test ECDH key";
priv_import_props.set_label( label );

// import to card
Botan::PKCS11::PKCS11_ECDH_PrivateKey priv_key( session, priv_import_props );

/************ export ECDH private key *************/
Botan::ECDH_PrivateKey exported = priv_key.export_key();

/************ import ECDH public key *************/

// set import properties
Botan::PKCS11::EC_PublicKeyImportProperties pub_import_props( priv_key_sw.
↪DER_domain(),
   Botan::DER_Encoder().encode( EC2OSP( priv_key_sw.public_point(),␣
↪Botan::PointGFp::UNCOMPRESSED ),
   Botan::OCTET_STRING ).get_contents_unlocked() );

pub_import_props.set_token( true );
pub_import_props.set_private( false );
pub_import_props.set_derive( true );

// label
label = "test ECDH pub key";
pub_import_props.set_label( label );

// import
Botan::PKCS11::PKCS11_ECDH_PublicKey pub_key( session, pub_import_props );

/************ export ECDH private key *************/
Botan::ECDH_PublicKey exported_pub = pub_key.export_key();

/************ generate ECDH private key *************/

Botan::PKCS11::EC_PrivateKeyGenerationProperties priv_generate_props;
priv_generate_props.set_token( true );
priv_generate_props.set_private( true );
priv_generate_props.set_derive( true );

Botan::PKCS11::PKCS11_ECDH_PrivateKey priv_key2( session,
   Botan::EC_Group( "secp256r1" ).DER_encode( Botan::EC_Group_Encoding::EC_
↪DOMPAR_ENC_OID ),
   priv_generate_props );

/************ generate ECDH key pair *************/

Botan::PKCS11::EC_PublicKeyGenerationProperties pub_generate_props(
   Botan::EC_Group( "secp256r1" ).DER_encode( Botan::EC_Group_Encoding::EC_
↪DOMPAR_ENC_OID ) );
```

(continues on next page)

(continued from previous page)

```
pub_generate_props.set_label( label + "_PUB_KEY" );
pub_generate_props.set_token( true );
pub_generate_props.set_derive( true );
pub_generate_props.set_private( false );
pub_generate_props.set_modifiable( true );

Botan::PKCS11::PKCS11_ECDH_KeyPair key_pair = Botan::PKCS11::generate_ecdh_
↪keypair(
   session, pub_generate_props, priv_generate_props );

/************ ECDH derive *************/

Botan::PKCS11::PKCS11_ECDH_KeyPair key_pair_other = Botan::PKCS11::generate_
↪ecdh_keypair(
   session, pub_generate_props, priv_generate_props );

Botan::PK_Key_Agreement ka( key_pair.second, rng, "Raw", "pkcs11" );
Botan::PK_Key_Agreement kb( key_pair_other.second, rng, "Raw", "pkcs11" );

Botan::SymmetricKey alice_key = ka.derive_key( 32,
   Botan::unlock( Botan::EC2OSP( key_pair_other.first.public_point(),
   Botan::PointGFp::UNCOMPRESSED ) ) );

Botan::SymmetricKey bob_key = kb.derive_key( 32,
   Botan::unlock( Botan::EC2OSP( key_pair.first.public_point(),
   Botan::PointGFp::UNCOMPRESSED ) ) );

bool eq = alice_key == bob_key;
```

29.2.8 RNG

The PKCS#11 RNG is defined in `<botan/p11_randomgenerator.h>`. The class *PKCS11_RNG* implements the `Hardware_RNG` interface.

class PKCS11_RNG : **public** Hardware_RNG

PKCS11_RNG(*Session* &*session*)
A PKCS#11 *Session* must be passed to instantiate a `PKCS11_RNG`.

void **randomize**(uint8_t *output*[], std::size_t *length*) **override**
Calls `C_GenerateRandom` to generate random data.

void **add_entropy**(**const** uint8_t *in*[], std::size_t *length*) **override**
Calls `C_SeedRandom` to add entropy to the random generation function of the token/middleware.

Code example:

```
Botan::PKCS11::PKCS11_RNG p11_rng( session );

/************ generate random data *************/
std::vector<uint8_t> random( 20 );
p11_rng.randomize( random.data(), random.size() );
```

(continues on next page)

(continued from previous page)

```
/************ add entropy *************/
Botan::AutoSeeded_RNG auto_rng;
auto auto_rng_random = auto_rng.random_vec( 20 );
p11_rng.add_entropy( auto_rng_random.data(), auto_rng_random.size() );

/************ use PKCS#11 RNG to seed HMAC_DRBG *************/
Botan::HMAC_DRBG drbg( Botan::MessageAuthenticationCode::create( "HMAC(SHA-
↪512)" ), p11_rng );
drbg.randomize( random.data(), random.size() );
```

29.2.9 Token Management Functions

The header file `<botan/p11.h>` also defines some free functions for token management:

void **initialize_token**(*Slot* &*slot*, **const** std::string &*label*, **const** secure_string &*so_pin*, **const** secure_string &*pin*)
: Initializes a token by passing a *Slot*, a `label` and the `so_pin` of the security officer.

void **change_pin**(*Slot* &*slot*, **const** secure_string &*old_pin*, **const** secure_string &*new_pin*)
: Change PIN with `old_pin` to `new_pin`.

void **change_so_pin**(*Slot* &*slot*, **const** secure_string &*old_so_pin*, **const** secure_string &*new_so_pin*)
: Change SO_PIN with `old_so_pin` to new `new_so_pin`.

void **set_pin**(*Slot* &*slot*, **const** secure_string &*so_pin*, **const** secure_string &*pin*)
: Sets user `pin` with `so_pin`.

Code example:

```
/************ set pin *************/

Botan::PKCS11::Module module( Middleware_path );

// only slots with connected token
std::vector<Botan::PKCS11::SlotId> slots = Botan::PKCS11::Slot::get_
↪available_slots( module, true );

// use first slot
Botan::PKCS11::Slot slot( module, slots.at( 0 ) );

Botan::PKCS11::secure_string so_pin = { '1', '2', '3', '4', '5', '6', '7', '8
↪' };
Botan::PKCS11::secure_string pin = { '1', '2', '3', '4', '5', '6' };
Botan::PKCS11::secure_string test_pin = { '6', '5', '4', '3', '2', '1' };

// set pin
Botan::PKCS11::set_pin( slot, so_pin, test_pin );

// change back
Botan::PKCS11::set_pin( slot, so_pin, pin );

/************ initialize *************/
Botan::PKCS11::initialize_token( slot, "Botan handbook example", so_pin, pin␣
↪);
```

(continues on next page)

(continued from previous page)

```
/************ change pin *************/
Botan::PKCS11::change_pin( slot, pin, test_pin );

// change back
Botan::PKCS11::change_pin( slot, test_pin, pin );

/************ change security officer pin *************/
Botan::PKCS11::change_so_pin( slot, so_pin, test_pin );

// change back
Botan::PKCS11::change_so_pin( slot, test_pin, so_pin );
```

29.2.10 X.509

The header file <botan/p11_x509.h> defines the property class `X509_CertificateProperties` and the class *PKCS11_X509_Certificate*.

class PKCS11_X509_Certificate : **public** *Object*, **public** *X509_Certificate*

PKCS11_X509_Certificate (*Session* &*session*, ObjectHandle *handle*)
Allows to use existing certificates on the token by passing a valid `ObjectHandle`.

PKCS11_X509_Certificate (*Session* &*session*, **const** X509_CertificateProperties &*props*)
Allows to import an existing X.509 certificate to the token with the `X509_CertificateProperties` passed in `props`.

Code example:

```
// load existing certificate
Botan::X509_Certificate root( "test.crt" );

// set props
Botan::PKCS11::X509_CertificateProperties props(
   Botan::DER_Encoder().encode( root.subject_dn() ).get_contents_unlocked(),␣
↪root.BER_encode() );

props.set_label( "Botan PKCS#11 test certificate" );
props.set_private( false );
props.set_token( true );

// import
Botan::PKCS11::PKCS11_X509_Certificate pkcs11_cert( session, props );

// load by handle
Botan::PKCS11::PKCS11_X509_Certificate pkcs11_cert2( session, pkcs11_cert.
↪handle() );
```

29.2.11 Tests

The PKCS#11 tests are not executed automatically because the depend on an external PKCS#11 module/middleware. The test tool has to be executed with `--pkcs11-lib=` followed with the path of the PKCS#11 module and a second

argument which controls the PKCS#11 tests that are executed. Passing `pkcs11` will execute all PKCS#11 tests but it's also possible to execute only a subset with the following arguments:

- pkcs11-ecdh
- pkcs11-ecdsa
- pkcs11-lowlevel
- pkcs11-manage
- pkcs11-module
- pkcs11-object
- pkcs11-rng
- pkcs11-rsa
- pkcs11-session
- pkcs11-slot
- pkcs11-x509

The following PIN and SO-PIN/PUK values are used in tests:

- PIN 123456
- SO-PIN/PUK 12345678

Warning: Unlike the CardOS (4.4, 5.0, 5.3), the aforementioned SO-PIN/PUK is inappropriate for Gemalto (IDPrime MD 3840) cards, as it must be a byte array of length 24. For this reason some of the tests for Gemalto card involving SO-PIN will fail. You run into a risk of exceding login attempts and as a result locking your card! Currently, specifying pin via command-line option is not implemented, and therefore the desired PIN must be modified in the header src/tests/test_pkcs11.h:

```
// SO PIN is expected to be set to "12345678" prior to running the tests
const std::string SO_PIN = "12345678";
const auto SO_PIN_SECVEC = Botan::PKCS11::secure_string(SO_PIN.begin(), SO_
↪PIN.end());
```

29.2.12 Tested/Supported Smartcards

You are very welcome to contribute your own test results for other testing environments or other cards.

Test results

Smartcard	Status	OS	Midleware	Botan	Errors
CardOS 4.4	mostly works	Windows 10, 64-bit, version 1709	API Version 5.4.9.77 (Cryptoki v2.11)	2.4.0, Cryptoki v2.40	[50]
CardOS 5.0	mostly works	Windows 10, 64-bit, version 1709	API Version 5.4.9.77 (Cryptoki v2.11)	2.4.0, Cryptoki v2.40	[51]

TRUSTED PLATFORM MODULE (TPM)

New in version 1.11.26.

Some computers come with a TPM, which is a small side processor which can perform certain operations which include RSA key generation and signing, a random number generator, accessing a small amount of NVRAM, and a set of PCRs which can be used to measure software state (this is TPMs most famous use, for authenticating a boot sequence).

The TPM NVRAM and PCR APIs are not supported by Botan at this time, patches welcome.

Currently only v1.2 TPMs are supported, and the only TPM library supported is TrouSerS (http://trousers.sourceforge.net/). Hopefully both of these limitations will be removed in a future release, in order to support newer TPM v2.0 systems. The current code has been tested with an ST TPM running in a Lenovo laptop.

Test for TPM support with the macro `BOTAN_HAS_TPM`, include `<botan/tpm.h>`.

First, create a connection to the TPM with a `TPM_Context`. The context is passed to all other TPM operations, and should remain alive as long as any other TPM object which the context was passed to is still alive, otherwise errors or even an application crash are possible. In the future, the API may change to using `shared_ptr` to remove this problem.

class TPM_Context

TPM_Context(pin_cb *cb*, **const** char **srk_password*)
The (somewhat improperly named) pin_cb callback type takes a std::string as an argument, which is an informative message for the user. It should return a string containing the password entered by the user.

Normally the SRK password is null. Use nullptr to signal this.

The TPM contains a RNG of unknown design or quality. If that doesn't scare you off, you can use it with `TPM_RNG` which implements the standard `RandomNumberGenerator` interface.

class TPM_RNG

TPM_RNG(*TPM_Context* &*ctx*)
Initialize a TPM RNG object. After initialization, reading from this RNG reads from the hardware? RNG on the TPM.

The v1.2 TPM uses only RSA, but because this key is implemented completely in hardware it uses a different private key type, with a somewhat different API to match the TPM's behavior.

class TPM_PrivateKey

TPM_PrivateKey(*TPM_Context* &*ctx*, size_t *bits*, **const** char **key_password*)

Create a new RSA key stored on the TPM. The bits should be either 1024 or 2048; the TPM interface hypothetically allows larger keys but in practice no v1.2 TPM hardware supports them.

The TPM processor is not fast, be prepared for this to take a while.

The key_password is the password to the TPM key ?

std::string **register_key**(TPM_Storage_Type *storage_type*)
Registers a key with the TPM. The storage_type can be either *TPM_Storage_Type::User* or *TPM_Storage_Type::System*. If System, the key is stored on the TPM itself. If User, it is stored on the local hard drive in a database maintained by an intermediate piece of system software (which actual interacts with the physical TPM on behalf of any number of applications calling the TPM API).

The TPM has only some limited space to store private keys and may reject requests to store the key.

In either case the key is encrypted with an RSA key which was generated on the TPM and which it will not allow to be exported. Thus (so goes the theory) without physically attacking the TPM

Returns a UUID which can be passed back to constructor below.

TPM_PrivateKey(*TPM_Context* &*ctx*, **const** std::string &*uuid*, TPM_Storage_Type *storage_type*)
Load a registered key. The UUID was returned by the `register_key` function.

std::vector<uint8_t> **export_blob**() **const**
Export the key as an encrypted blob. This blob can later be presented back to the same TPM to load the key.

TPM_PrivateKey(*TPM_Context* &*ctx*, **const** std::vector<uint8_t> &*blob*)
Load a TPM key previously exported as a blob with `export_blob`.

std::unique_ptr<Public_Key> **public_key**() **const**
Return the public key associated with this TPM private key.

TPM does not store public keys, nor does it support signature verification.

TSS_HKEY **handle**() **const**
Returns the bare TSS key handle. Use if you need to call the raw TSS API.

A `TPM_PrivateKey` can be passed to a `PK_Signer` constructor and used to sign messages just like any other key. Only PKCS #1 v1.5 signatures are supported by the v1.2 TPM.

std::vector<std::string> *TPM_PrivateKey*::**registered_keys**(*TPM_Context* &*ctx*)
This static function returns the list of all keys (in URL format) registered with the system

CHAPTER

THIRTYONE

ONE TIME PASSWORDS

One time password schemes are a user authentication method that relies on a fixed secret key which is used to derive a sequence of short passwords, each of which is accepted only once. Commonly this is used to implement two-factor authentication (2FA), where the user authenticates using both a conventional password (or a public key signature) and an OTP generated by a small device such as a mobile phone.

Botan implements the HOTP and TOTP schemes from RFC 4226 and 6238.

Since the range of possible OTPs is quite small, applications must rate limit OTP authentication attempts to some small number per second. Otherwise an attacker could quickly try all 1000000 6-digit OTPs in a brief amount of time.

31.1 HOTP

HOTP generates OTPs that are a short numeric sequence, between 6 and 8 digits (most applications use 6 digits), created using the HMAC of a 64-bit counter value. If the counter ever repeats the OTP will also repeat, thus both parties must assure the counter only increments and is never repeated or decremented. Thus both client and server must keep track of the next counter expected.

Anyone with access to the client-specific secret key can authenticate as that client, so it should be treated with the same security consideration as would be given to any other symmetric key or plaintext password.

class HOTP

Implement counter-based OTP

HOTP(**const** SymmetricKey &*key*, **const** std::string &*hash_algo* = "SHA-1", size_t *digits* = 6)

Initialize an HOTP instance with a secret key (specific to each client), a hash algorithm (must be SHA-1, SHA-256, or SHA-512), and the number of digits with each OTP (must be 6, 7, or 8).

In RFC 4226, HOTP is only defined with SHA-1, but many HOTP implementations support SHA-256 as an extension. The collision attacks on SHA-1 do not have any known effect on HOTP's security.

uint32_t **generate_hotp**(uint64_t *counter*)

Return the OTP associated with a specific counter value.

std::pair<bool, uint64_t> **verify_hotp**(uint32_t *otp*, uint64_t *starting_counter*, size_t *resync_range* = 0)

Check if a provided OTP matches the one that should be generated for the specified counter.

The *starting_counter* should be the counter of the last successful authentication plus 1. If *resync_resync* is greater than 0, some number of counter values above *starting_counter* will also be checked if necessary. This is useful for instance when a client mistypes an OTP on entry; the authentication will fail so the server will not update its counter, but the client device will subsequently show the OTP for the next counter. Depending on the environment a *resync_range* of 3 to 10 might be appropriate.

Returns a pair of (is_valid,next_counter_to_use). If the OTP is invalid then always returns (false,starting_counter), since the last successful authentication counter has not changed.

31.2 TOTP

TOTP is based on the same algorithm as HOTP, but instead of a counter a timestamp is used.

class TOTP

TOTP(**const** SymmetricKey &*key*, **const** std::string &*hash_algo* = "SHA-1", size_t *digits* = 6, size_t *time_step* = 30)
Setup to perform TOTP authentication using secret key *key*.

uint32_t **generate_totp**(std::chrono::system_clock::time_point *time_point*)

uint32_t **generate_totp**(uint64_t *unix_time*)
Generate and return a TOTP code based on a timestamp.

bool **verify_totp**(uint32_t *otp*, std::chrono::system_clock::time_point *time*, size_t *clock_drift_accepted* = 0)

bool **verify_totp**(uint32_t *otp*, uint64_t *unix_time*, size_t *clock_drift_accepted* = 0)
Return true if the provided OTP code is correct for the provided timestamp. If required, use *clock_drift_accepted* to deal with the client and server having slightly different clocks.

CHAPTER

THIRTYTWO

FFI (C BINDING)

New in version 1.11.14.

Botan's ffi module provides a C89 binding intended to be easily usable with other language's foreign function interface (FFI) libraries. For instance the included Python wrapper uses Python's `ctypes` module and the C89 API. This API is of course also useful for programs written directly in C.

Code examples can be found in the tests (https://github.com/randombit/botan/blob/master/src/tests/test_ffi.cpp).

32.1 Return Codes

Almost all functions in the Botan C interface return an `int` error code. The only exceptions are a handful of functions (like *botan_ffi_api_version*) which cannot fail in any circumstances.

The FFI functions return a non-negative integer (usually 0) to indicate success, or a negative integer to represent an error. A few functions (like *botan_block_cipher_block_size*) return positive integers instead of zero on success.

The error codes returned in certain error situations may change over time. This especially applies to very generic errors like *BOTAN_FFI_ERROR_EXCEPTION_THROWN* and *BOTAN_FFI_ERROR_UNKNOWN_ERROR*. For instance, before 2.8, setting an invalid key length resulted in *BOTAN_FFI_ERROR_EXCEPTION_THROWN* but now this is specially handled and returns *BOTAN_FFI_ERROR_INVALID_KEY_LENGTH* instead.

The following enum values are defined in the FFI header:

enumerator BOTAN_FFI_SUCCESS = 0
: Generally returned to indicate success

enumerator BOTAN_FFI_INVALID_VERIFIER = 1
: Note this value is positive, but still represents an error condition. In indicates that the function completed successfully, but the value provided was not correct. For example *botan_bcrypt_is_valid* returns this value if the password did not match the hash.

enumerator BOTAN_FFI_ERROR_INVALID_INPUT = -1
: The input was invalid. (Currently this error return is not used.)

enumerator BOTAN_FFI_ERROR_BAD_MAC = -2
: While decrypting in an AEAD mode, the tag failed to verify.

enumerator BOTAN_FFI_ERROR_INSUFFICIENT_BUFFER_SPACE = -10
: Functions which write a variable amount of space return this if the indicated buffer length was insufficient to write the data. In that case, the output length parameter is set to the size that is required.

enumerator BOTAN_FFI_ERROR_EXCEPTION_THROWN = -20
: An exception was thrown while processing this request, but no further details are available.

Note: If the environment variable `BOTAN_FFI_PRINT_EXCEPTIONS` is set, then any exception which is caught by the FFI layer will first print the exception message to stderr before returning an error. This is sometimes useful for debugging.

enumerator BOTAN_FFI_ERROR_OUT_OF_MEMORY = -21
Memory allocation failed

enumerator BOTAN_FFI_ERROR_BAD_FLAG = -30
A value provided in a *flag* variable was unknown.

enumerator BOTAN_FFI_ERROR_NULL_POINTER = -31
A null pointer was provided as an argument where that is not allowed.

enumerator BOTAN_FFI_ERROR_BAD_PARAMETER = -32
An argument did not match the function.

enumerator BOTAN_FFI_ERROR_KEY_NOT_SET = -33
An object that requires a key normally must be keyed before use (eg before encrypting or MACing data). If this is not done, the operation will fail and return this error code.

enumerator BOTAN_FFI_ERROR_INVALID_KEY_LENGTH = -34
An invalid key length was provided with a call to `x_set_key`.

enumerator BOTAN_FFI_ERROR_NOT_IMPLEMENTED = -40
This is returned if the functionality is not available for some reason. For example if you call *botan_hash_init* with a named hash function which is not enabled, this error is returned.

enumerator BOTAN_FFI_ERROR_INVALID_OBJECT = -50
This is used if an object provided did not match the function. For example calling *botan_hash_destroy* on a `botan_rng_t` object will cause this return.

enumerator BOTAN_FFI_ERROR_UNKNOWN_ERROR = -100
Something bad happened, but we are not sure why or how.

32.2 Versioning

uint32_t **botan_ffi_api_version**()
Returns the version of the currently supported FFI API. This is expressed in the form YYYYMMDD of the release date of this version of the API.

int **botan_ffi_supports_api**(uint32_t *version*)
Returns 0 iff the FFI version specified is supported by this library. Otherwise returns -1. The expression botan_ffi_supports_api(botan_ffi_api_version()) will always evaluate to 0. A particular version of the library may also support other (older) versions of the FFI API.

const char ***botan_version_string**()
Returns a free-form string describing the version. The return value is a statically allocated string.

uint32_t **botan_version_major**()
Returns the major version of the library

uint32_t **botan_version_minor**()
Returns the minor version of the library

uint32_t **botan_version_patch**()
Returns the patch version of the library

uint32_t **botan_version_datestamp**()
Returns the date this version was released as an integer YYYYMMDD, or 0 if an unreleased version

32.2.1 FFI Versions

This maps the FFI API version to the first version of the library that supported it.

FFI Version	Supported Starting
20180713	2.8.0
20170815	2.3.0
20170327	2.1.0
20150515	2.0.0

32.3 Utility Functions

int **botan_same_mem**(**const** uint8_t *x, **const** uint8_t *y, size_t *len*)
Returns 0 if *x[0..len] == y[0..len]*, -1 otherwise.

int **botan_hex_encode**(**const** uint8_t *x, size_t *len*, char *out, uint32_t *flags*)
Performs hex encoding of binary data in *x* of size *len* bytes. The output buffer *out* must be of at least *x*2* bytes in size. If *flags* contains `BOTAN_FFI_HEX_LOWER_CASE`, hex encoding will only contain lower-case letters, upper-case letters otherwise. Returns 0 on success, 1 otherwise.

int **botan_hex_decode**(**const** char *hex_str, size_t *in_len*, uint8_t *out, size_t *out_len*)
Hex decode some data

32.4 Random Number Generators

typedef opaque ***botan_rng_t**
An opaque data type for a random number generator. Don't mess with it.

int **botan_rng_init**(*botan_rng_t* *rng, **const** char *rng_type*)
Initialize a random number generator object from the given *rng_type*: "system" (or `nullptr`): `System_RNG`, "user": `AutoSeeded_RNG`, "user-threadsafe": serialized `AutoSeeded_RNG`, "null": `Null_RNG` (always fails), "rdrand": `RDRAND_RNG` (if available)

int **botan_rng_get**(*botan_rng_t rng*, uint8_t *out, size_t *out_len*)
Get random bytes from a random number generator.

int **botan_rng_reseed**(*botan_rng_t rng*, size_t *bits*)
Reseeds the random number generator with *bits* number of bits from the *System_RNG*.

int **botan_rng_reseed_from_rng**(*botan_rng_t rng*, *botan_rng_t src*, size_t *bits*)
Reseeds the random number generator with *bits* number of bits taken from the given source RNG.

int **botan_rng_add_entropy**(*botan_rng_t rng*, **const** uint8_t *seed*[], size_t *len*)
Adds the provided seed material to the internal RNG state.

This call may be ignored by certain RNG instances (such as RDRAND or, on some systems, the system RNG).

int **botan_rng_destroy**(*botan_rng_t rng*)
Destroy the object created by *botan_rng_init*.

32.5 Block Ciphers

New in version 2.1.0.

This is a 'raw' interface to ECB mode block ciphers. Most applications want the higher level cipher API which provides authenticated encryption. This API exists as an escape hatch for applications which need to implement custom primitives using a PRP.

typedef opaque ***botan_block_cipher_t**
An opaque data type for a block cipher. Don't mess with it.

int **botan_block_cipher_init**(*botan_block_cipher_t* **bc*, **const** char **cipher_name*)
Create a new cipher mode object, *cipher_name* should be for example "AES-128" or "Threefish-512"

int **botan_block_cipher_block_size**(*botan_block_cipher_t bc*)
Return the block size of this cipher.

int **botan_block_cipher_name**(*botan_block_cipher_t cipher*, char **name*, size_t **name_len*)
Return the name of this block cipher algorithm, which may nor may not exactly match what was passed to *botan_block_cipher_init*.

int **botan_block_cipher_get_keyspec**(*botan_block_cipher_t cipher*, size_t **out_minimum_keylength*, size_t **out_maximum_keylength*, size_t **out_keylength_modulo*)
Return the limits on the key which can be provided to this cipher. If any of the parameters are null, no output is written to that field. This allows retrieving only (say) the maximum supported keylength, if that is the only information needed.

int **botan_block_cipher_clear**(*botan_block_cipher_t bc*)
Clear the internal state (such as keys) of this cipher object, but do not deallocate it.

int **botan_block_cipher_set_key**(*botan_block_cipher_t bc*, **const** uint8_t *key*[], size_t *key_len*)
Set the cipher key, which is required before encrypting or decrypting.

int **botan_block_cipher_encrypt_blocks**(*botan_block_cipher_t bc*, **const** uint8_t *in*[], uint8_t *out*[], size_t *blocks*)
The key must have been set first with *botan_block_cipher_set_key*. Encrypt *blocks* blocks of data stored in *in* and place the ciphertext into *out*. The two parameters may be the same buffer, but must not overlap.

int **botan_block_cipher_decrypt_blocks**(*botan_block_cipher_t bc*, **const** uint8_t *in*[], uint8_t *out*[], size_t *blocks*)
The key must have been set first with *botan_block_cipher_set_key*. Decrypt *blocks* blocks of data stored in *in* and place the ciphertext into *out*. The two parameters may be the same buffer, but must not overlap.

int **botan_block_cipher_destroy**(*botan_block_cipher_t rng*)
Destroy the object created by *botan_block_cipher_init*.

32.6 Hash Functions

typedef opaque ***botan_hash_t**
An opaque data type for a hash. Don't mess with it.

botan_hash_t **botan_hash_init**(**const** char **hash*, uint32_t *flags*)
Creates a hash of the given name, e.g., "SHA-384". Returns null on failure. Flags should always be zero in this version of the API.

int **botan_hash_destroy**(*botan_hash_t hash*)
Destroy the object created by *botan_hash_init*.

int **botan_hash_name**(*botan_hash_t hash*, char **name*, size_t **name_len*)
Write the name of the hash function to the provided buffer.

int **botan_hash_copy_state**(*botan_hash_t *dest*, **const** *botan_hash_t source*)
Copies the state of the hash object to a new hash object.

int **botan_hash_clear**(*botan_hash_t hash*)
Reset the state of this object back to clean, as if no input has been supplied.

size_t **botan_hash_output_length**(*botan_hash_t hash*)
Return the output length of the hash function.

int **botan_hash_update**(*botan_hash_t hash*, **const** uint8_t **input*, size_t *len*)
Add input to the hash computation.

int **botan_hash_final**(*botan_hash_t hash*, uint8_t *out*[])
Finalize the hash and place the output in out. Exactly `botan_hash_output_length` bytes will be written.

32.7 Message Authentication Codes

typedef opaque ***botan_mac_t**
An opaque data type for a MAC. Don't mess with it, but do remember to set a random key first.

botan_mac_t **botan_mac_init**(**const** char **mac*, uint32_t *flags*)
Creates a MAC of the given name, e.g., "HMAC(SHA-384)". Returns null on failure. Flags should always be zero in this version of the API.

int **botan_mac_destroy**(*botan_mac_t mac*)
Destroy the object created by `botan_mac_init`.

int **botan_mac_clear**(*botan_mac_t mac*)
Reset the state of this object back to clean, as if no key and input have been supplied.

size_t **botan_mac_output_length**(*botan_mac_t mac*)
Return the output length of the MAC.

int **botan_mac_set_key**(*botan_mac_t mac*, **const** uint8_t **key*, size_t *key_len*)
Set the random key.

int **botan_mac_update**(*botan_mac_t mac*, uint8_t *buf*[], size_t *len*)
Add input to the MAC computation.

int **botan_mac_final**(*botan_mac_t mac*, uint8_t *out*[], size_t **out_len*)
Finalize the MAC and place the output in out. Exactly `botan_mac_output_length` bytes will be written.

32.8 Symmetric Ciphers

typedef opaque ***botan_cipher_t**
An opaque data type for a symmetric cipher object. Don't mess with it, but do remember to set a random key first. And please use an AEAD.

botan_cipher_t **botan_cipher_init**(**const** char **cipher_name*, uint32_t *flags*)
Create a cipher object from a name such as "AES-256/GCM" or "Serpent/OCB".

Flags is a bitfield; the low bitof `flags` specifies if encrypt or decrypt, ie use 0 for encryption and 1 for decryption.

int **botan_cipher_destroy**(*botan_cipher_t cipher*)

int **botan_cipher_clear**(*botan_cipher_t hash*)

int **botan_cipher_set_key**(*botan_cipher_t cipher*, **const** uint8_t **key*, size_t *key_len*)

int **botan_cipher_is_authenticated**(*botan_cipher_t cipher*)

size_t **botan_cipher_get_tag_length**(*botan_cipher_t cipher*, size_t **tag_len*)
Write the tag length of the cipher to `tag_len`. This will be zero for non-authenticated ciphers.

int **botan_cipher_valid_nonce_length**(*botan_cipher_t cipher*, size_t *nl*)
Returns 1 if the nonce length is valid, or 0 otherwise. Returns -1 on error (such as the cipher object being invalid).

size_t **botan_cipher_get_default_nonce_length**(*botan_cipher_t cipher*, size_t **nl*)
Return the default nonce length

int **botan_cipher_set_associated_data**(*botan_cipher_t cipher*, **const** uint8_t **ad*, size_t *ad_len*)
Set associated data. Will fail unless the cipher is an AEAD.

int **botan_cipher_start**(*botan_cipher_t cipher*, **const** uint8_t **nonce*, size_t *nonce_len*)
Start processing a message using the provided nonce.

int **botan_cipher_update**(*botan_cipher_t cipher*, uint32_t *flags*, uint8_t *output*[], size_t *output_size*, size_t **output_written*, **const** uint8_t *input_bytes*[], size_t *input_size*, size_t **input_consumed*)
Encrypt or decrypt data.

32.9 PBKDF

int **botan_pbkdf**(**const** char **pbkdf_algo*, uint8_t *out*[], size_t *out_len*, **const** char **passphrase*, **const** uint8_t *salt*[], size_t *salt_len*, size_t *iterations*)
Derive a key from a passphrase for a number of iterations using the given PBKDF algorithm, e.g., "PBKDF2".

int **botan_pbkdf_timed**(**const** char **pbkdf_algo*, uint8_t *out*[], size_t *out_len*, **const** char **passphrase*, **const** uint8_t *salt*[], size_t *salt_len*, size_t *milliseconds_to_run*, size_t **out_iterations_used*)
Derive a key from a passphrase using the given PBKDF algorithm, e.g., "PBKDF2". If *out_iterations_used* is zero, instead the PBKDF is run until *milliseconds_to_run* milliseconds have passed. In this case, the number of iterations run will be written to *out_iterations_used*.

32.10 KDF

int **botan_kdf**(**const** char **kdf_algo*, uint8_t *out*[], size_t *out_len*, **const** uint8_t *secret*[], size_t *secret_len*, **const** uint8_t *salt*[], size_t *salt_len*, **const** uint8_t *label*[], size_t *label_len*)
Derive a key using the given KDF algorithm, e.g., "SP800-56C". The derived key of length *out_len* bytes will be placed in *out*.

32.11 Multiple Precision Integers

typedef opaque ***botan_mp_t**
An opaque data type for a multiple precision integer. Don't mess with it.

int **botan_mp_init**(*botan_mp_t *mp*)
Initialize a `botan_mp_t`. Initial value is zero, use *botan_mp_set_X* to load a value.

int **botan_mp_destroy**(*botan_mp_t mp*)
Free a `botan_mp_t`

int **botan_mp_to_hex**(*botan_mp_t mp*, char **out*)
Writes exactly `botan_mp_num_bytes(mp)*2 + 1` bytes to out

int **botan_mp_to_str**(*botan_mp_t mp*, uint8_t *base*, char **out*, size_t **out_len*)
Base can be either 10 or 16.

int **botan_mp_set_from_int**(*botan_mp_t mp*, int *initial_value*)
Set `botan_mp_t` from an integer value.

int **botan_mp_set_from_mp**(*botan_mp_t dest*, *botan_mp_t source*)
Set `botan_mp_t` from another MP.

int **botan_mp_set_from_str**(*botan_mp_t dest*, **const** char **str*)
Set `botan_mp_t` from a string. Leading prefix of "0x" is accepted.

int **botan_mp_num_bits**(*botan_mp_t n*, size_t **bits*)
Return the size of `n` in bits.

int **botan_mp_num_bytes**(*botan_mp_t n*, size_t **uint8_ts*)
Return the size of `n` in bytes.

int **botan_mp_to_bin**(*botan_mp_t mp*, uint8_t *vec*[])
Writes exactly `botan_mp_num_bytes(mp)` to `vec`.

int **botan_mp_from_bin**(*botan_mp_t mp*, **const** uint8_t *vec*[], size_t *vec_len*)
Loads `botan_mp_t` from a binary vector (as produced by `botan_mp_to_bin`).

int **botan_mp_is_negative**(*botan_mp_t mp*)
Return 1 if `mp` is negative, otherwise 0.

int **botan_mp_flip_sign**(*botan_mp_t mp*)
Flip the sign of `mp`.

int **botan_mp_add**(*botan_mp_t result*, *botan_mp_t x*, *botan_mp_t y*)
Add two `botan_mp_t``s and store the output in ``result`.

int **botan_mp_sub**(*botan_mp_t result*, *botan_mp_t x*, *botan_mp_t y*)
Subtract two `botan_mp_t``s and store the output in ``result`.

int **botan_mp_mul**(*botan_mp_t result*, *botan_mp_t x*, *botan_mp_t y*)
Multiply two `botan_mp_t``s and store the output in ``result`.

int **botan_mp_div**(*botan_mp_t quotient*, *botan_mp_t remainder*, *botan_mp_t x*, *botan_mp_t y*)
Divide `x` by `y` and store the output in `quotient` and `remainder`.

int **botan_mp_mod_mul**(*botan_mp_t result*, *botan_mp_t x*, *botan_mp_t y*, *botan_mp_t mod*)
Set `result` to `x` times `y` modulo `mod`.

int **botan_mp_equal**(*botan_mp_t x*, *botan_mp_t y*)
Return 1 if `x` is equal to `y`, 0 if `x` is not equal to `y`

int **botan_mp_is_zero**(**const** *botan_mp_t x*)
Return 1 if `x` is equal to zero, otherwise 0.

int **botan_mp_is_odd**(**const** *botan_mp_t x*)
Return 1 if `x` is odd, otherwise 0.

int **botan_mp_is_even**(**const** *botan_mp_t x*)
Return 1 if `x` is even, otherwise 0.

int **botan_mp_is_positive**(**const** *botan_mp_t x*)
Return 1 if x is greater than or equal to zero.

int **botan_mp_is_negative**(**const** *botan_mp_t x*)
Return 1 if x is less than zero.

int **botan_mp_to_uint32**(**const** *botan_mp_t x*, uint32_t **val*)
If x fits in a 32-bit integer, set val to it and return 0. If x is out of range an error is returned.

int **botan_mp_cmp**(int **result*, *botan_mp_t x*, *botan_mp_t y*)
Three way comparison: set result to -1 if x is less than y, 0 if x is equal to y, and 1 if x is greater than y.

int **botan_mp_swap**(*botan_mp_t x*, *botan_mp_t y*)
Swap two botan_mp_t values.

int **botan_mp_powmod**(*botan_mp_t out*, *botan_mp_t base*, *botan_mp_t exponent*, *botan_mp_t modulus*)
Modular exponentiation.

int **botan_mp_lshift**(*botan_mp_t out*, *botan_mp_t in*, size_t *shift*)
Left shift by specified bit count, place result in out.

int **botan_mp_rshift**(*botan_mp_t out*, *botan_mp_t in*, size_t *shift*)
Right shift by specified bit count, place result in out.

int **botan_mp_mod_inverse**(*botan_mp_t out*, *botan_mp_t in*, *botan_mp_t modulus*)
Compute modular inverse. If no modular inverse exists (for instance because in and modulus are not relatively prime), then sets out to -1.

int **botan_mp_rand_bits**(*botan_mp_t rand_out*, *botan_rng_t rng*, size_t *bits*)
Create a random botan_mp_t of the specified bit size.

int **botan_mp_rand_range**(*botan_mp_t rand_out*, *botan_rng_t rng*, *botan_mp_t lower_bound*, *botan_mp_t upper_bound*)
Create a random botan_mp_t within the provided range.

int **botan_mp_gcd**(*botan_mp_t out*, *botan_mp_t x*, *botan_mp_t y*)
Compute the greatest common divisor of x and y.

int **botan_mp_is_prime**(*botan_mp_t n*, *botan_rng_t rng*, size_t *test_prob*)
Test if n is prime. The algorithm used (Miller-Rabin) is probabilistic, set test_prob to the desired assurance level. For example if test_prob is 64, then sufficient Miller-Rabin iterations will run to assure there is at most a 1/2**64 chance that n is composite.

int **botan_mp_get_bit**(*botan_mp_t n*, size_t *bit*)
Returns 0 if the specified bit of n is not set, 1 if it is set.

int **botan_mp_set_bit**(*botan_mp_t n*, size_t *bit*)
Set the specified bit of n

int **botan_mp_clear_bit**(*botan_mp_t n*, size_t *bit*)
Clears the specified bit of n

32.12 Password Hashing

int **botan_bcrypt_generate**(uint8_t **out*, size_t **out_len*, **const** char **password*, *botan_rng_t rng*, size_t *work_factor*, uint32_t *flags*)
Create a password hash using Bcrypt. The output buffer *out* should be of length 64 bytes. The output is formatted bcrypt $2a$...

int **botan_bcrypt_is_valid**(**const** char *_pass_, **const** char *_hash_)
Check a previously created password hash. Returns BOTAN_SUCCESS if if this password/hash combination is valid, *BOTAN_FFI_INVALID_VERIFIER* if the combination is not valid (but otherwise well formed), negative on error.

32.13 Public Key Creation, Import and Export

typedef opaque ***botan_privkey_t**
An opaque data type for a private key. Don't mess with it.

int **botan_privkey_create**(*botan_privkey_t* *_key_, **const** char *_algo_name_, **const** char *_algo_params_, *botan_rng_t* _rng_)

int **botan_privkey_create_rsa**(*botan_privkey_t* *_key_, *botan_rng_t* _rng_, size_t _n_bits_)

int **botan_privkey_create_ecdsa**(*botan_privkey_t* *_key_, *botan_rng_t* _rng_, **const** char *_params_)

int **botan_privkey_create_ecdh**(*botan_privkey_t* *_key_, *botan_rng_t* _rng_, **const** char *_params_)

int **botan_privkey_create_mceliece**(*botan_privkey_t* *_key_, *botan_rng_t* _rng_, size_t _n_, size_t _t_)

int **botan_privkey_create_dh**(*botan_privkey_t* *_key_, *botan_rng_t* _rng_, **const** char *_params_)

int **botan_privkey_load**(*botan_privkey_t* *_key_, *botan_rng_t* _rng_, **const** uint8_t _bits_[], size_t _len_, **const** char *_password_)

int **botan_privkey_destroy**(*botan_privkey_t* _key_)

int **botan_privkey_export**(*botan_privkey_t* _key_, uint8_t _out_[], size_t *_out_len_, uint32_t _flags_)

int **botan_privkey_export_encrypted**(*botan_privkey_t* _key_, uint8_t _out_[], size_t *_out_len_, *botan_rng_t* _rng_, **const** char *_passphrase_, **const** char *_encryption_algo_, uint32_t _flags_)
Deprecated, use botan_privkey_export_encrypted_msec or botan_privkey_export_encrypted_iter

typedef opaque ***botan_pubkey_t**
An opaque data type for a public key. Don't mess with it.

int **botan_pubkey_load**(*botan_pubkey_t* *_key_, **const** uint8_t _bits_[], size_t _len_)

int **botan_privkey_export_pubkey**(*botan_pubkey_t* *_out_, *botan_privkey_t* _in_)

int **botan_pubkey_export**(*botan_pubkey_t* _key_, uint8_t _out_[], size_t *_out_len_, uint32_t _flags_)

int **botan_pubkey_algo_name**(*botan_pubkey_t* _key_, char _out_[], size_t *_out_len_)

int **botan_pubkey_estimated_strength**(*botan_pubkey_t* _key_, size_t *_estimate_)

int **botan_pubkey_fingerprint**(*botan_pubkey_t* _key_, **const** char *_hash_, uint8_t _out_[], size_t *_out_len_)

int **botan_pubkey_destroy**(*botan_pubkey_t* _key_)

int **botan_pubkey_get_field**(*botan_mp_t* _output_, *botan_pubkey_t* _key_, **const** char *_field_name_)
Read an algorithm specific field from the public key object, placing it into output. For example "n" or "e" for RSA keys or "p", "q", "g", and "y" for DSA keys.

int **botan_privkey_get_field**(*botan_mp_t* _output_, *botan_privkey_t* _key_, **const** char *_field_name_)
Read an algorithm specific field from the private key object, placing it into output. For example "p" or "q" for RSA keys, or "x" for DSA keys or ECC keys.

32.14 RSA specific functions

int **botan_privkey_rsa_get_p**(*botan_mp_t p*, *botan_privkey_t rsa_key*)
Set p to the first RSA prime.

int **botan_privkey_rsa_get_q**(*botan_mp_t q*, *botan_privkey_t rsa_key*)
Set q to the second RSA prime.

int **botan_privkey_rsa_get_d**(*botan_mp_t d*, *botan_privkey_t rsa_key*)
Set d to the RSA private exponent.

int **botan_privkey_rsa_get_n**(*botan_mp_t n*, *botan_privkey_t rsa_key*)
Set n to the RSA modulus.

int **botan_privkey_rsa_get_e**(*botan_mp_t e*, *botan_privkey_t rsa_key*)
Set e to the RSA public exponent.

int **botan_pubkey_rsa_get_e**(*botan_mp_t e*, *botan_pubkey_t rsa_key*)
Set e to the RSA public exponent.

int **botan_pubkey_rsa_get_n**(*botan_mp_t n*, *botan_pubkey_t rsa_key*)
Set n to the RSA modulus.

int **botan_privkey_load_rsa**(*botan_privkey_t *key*, *botan_mp_t p*, *botan_mp_t q*, *botan_mp_t e*)
Initialize a private RSA key using parameters p, q, and e.

int **botan_pubkey_load_rsa**(*botan_pubkey_t *key*, *botan_mp_t n*, *botan_mp_t e*)
Initialize a public RSA key using parameters n and e.

32.15 DSA specific functions

int **botan_privkey_load_dsa**(*botan_privkey_t *key*, *botan_mp_t p*, *botan_mp_t q*, *botan_mp_t g*, *botan_mp_t x*)
Initialize a private DSA key using group parameters p, q, and g and private key x.

int **botan_pubkey_load_dsa**(*botan_pubkey_t *key*, *botan_mp_t p*, *botan_mp_t q*, *botan_mp_t g*, *botan_mp_t y*)
Initialize a private DSA key using group parameters p, q, and g and public key y.

32.16 ElGamal specific functions

int **botan_privkey_load_elgamal**(*botan_privkey_t *key*, *botan_mp_t p*, *botan_mp_t g*, *botan_mp_t x*)
Initialize a private ElGamal key using group parameters p and g and private key x.

int **botan_pubkey_load_elgamal**(*botan_pubkey_t *key*, *botan_mp_t p*, *botan_mp_t g*, *botan_mp_t y*)
Initialize a public ElGamal key using group parameters p and g and public key y.

32.17 Diffie-Hellman specific functions

int **botan_privkey_load_dh**(*botan_privkey_t *key*, *botan_mp_t p*, *botan_mp_t g*, *botan_mp_t x*)
Initialize a private Diffie-Hellman key using group parameters p and g and private key x.

int **botan_pubkey_load_dh**(*botan_pubkey_t *key*, *botan_mp_t p*, *botan_mp_t g*, *botan_mp_t y*)
Initialize a public Diffie-Hellman key using group parameters p and g and public key y.

32.18 Public Key Encryption/Decryption

typedef opaque ***botan_pk_op_encrypt_t**
An opaque data type for an encryption operation. Don't mess with it.

int **botan_pk_op_encrypt_create**(*botan_pk_op_encrypt_t* **op*, *botan_pubkey_t key*, **const** char **padding*, uint32_t *flags*)
Create a new operation object which can be used to encrypt using the provided key and the specified padding scheme (such as "OAEP(SHA-256)" for use with RSA). Flags should be 0 in this version.

int **botan_pk_op_encrypt_destroy**(*botan_pk_op_encrypt_t op*)
Destroy the object.

int **botan_pk_op_encrypt_output_length**(*botan_pk_op_encrypt_t op*, size_t *ptext_len*, size_t **ctext_len*)
Returns an upper bound on the output length if a plaintext of length `ptext_len` is encrypted with this key/parameter setting. This allows correctly sizing the buffer that is passed to *botan_pk_op_encrypt*.

int **botan_pk_op_encrypt**(*botan_pk_op_encrypt_t op*, *botan_rng_t rng*, uint8_t *out*[], size_t **out_len*, **const** uint8_t *plaintext*[], size_t *plaintext_len*)
Encrypt the provided data using the key, placing the output in *out*. If *out* is NULL, writes the length of what the ciphertext would have been to **out_len*. However this is computationally expensive (the encryption actually occurs, then the result is discarded), so it is better to use *botan_pk_op_encrypt_output_length* to correctly size the buffer.

typedef opaque ***botan_pk_op_decrypt_t**
An opaque data type for a decryption operation. Don't mess with it.

int **botan_pk_op_decrypt_create**(*botan_pk_op_decrypt_t* **op*, *botan_privkey_t key*, **const** char **padding*, uint32_t *flags*)

int **botan_pk_op_decrypt_destroy**(*botan_pk_op_decrypt_t op*)

int **botan_pk_op_decrypt_output_length**(*botan_pk_op_decrypt_t op*, size_t *ctext_len*, size_t **ptext_len*)
For a given ciphertext length, returns the upper bound on the size of the plaintext that might be enclosed. This allows properly sizing the output buffer passed to *botan_pk_op_decrypt*.

int **botan_pk_op_decrypt**(*botan_pk_op_decrypt_t op*, uint8_t *out*[], size_t **out_len*, uint8_t *ciphertext*[], size_t *ciphertext_len*)

32.19 Signature Generation

typedef opaque ***botan_pk_op_sign_t**
An opaque data type for a signature generation operation. Don't mess with it.

int **botan_pk_op_sign_create**(*botan_pk_op_sign_t* **op*, *botan_privkey_t key*, **const** char **hash_and_padding*, uint32_t *flags*)
Create a signature operator for the provided key. The padding string specifies what hash function and padding should be used, for example "PKCS1v15(SHA-256)" or "EMSA1(SHA-384)".

int **botan_pk_op_sign_destroy**(*botan_pk_op_sign_t op*)
Destroy an object created by *botan_pk_op_sign_create*.

int **botan_pk_op_sign_output_length**(*botan_pk_op_sign_t op*, size_t **sig_len*)
Writes the length of the signatures that this signer will produce. This allows properly sizing the buffer passed to *botan_pk_op_sign_finish*.

int **botan_pk_op_sign_update**(*botan_pk_op_sign_t op*, **const** uint8_t *in*[], size_t *in_len*)
Add bytes of the message to be signed.

int **botan_pk_op_sign_finish**(*botan_pk_op_sign_t op*, *botan_rng_t rng*, uint8_t *sig*[], size_t **sig_len*)
Produce a signature over all of the bytes passed to `botan_pk_op_sign_update`. Afterwards, the sign operator is reset and may be used to sign a new message.

32.20 Signature Verification

typedef opaque ***botan_pk_op_verify_t**
An opaque data type for a signature verification operation. Don't mess with it.

int **botan_pk_op_verify_create**(*botan_pk_op_verify_t* **op*, *botan_pubkey_t key*, **const** char **hash_and_padding*, uint32_t *flags*)

int **botan_pk_op_verify_destroy**(*botan_pk_op_verify_t op*)

int **botan_pk_op_verify_update**(*botan_pk_op_verify_t op*, **const** uint8_t *in*[], size_t *in_len*)
Add bytes of the message to be verified

int **botan_pk_op_verify_finish**(*botan_pk_op_verify_t op*, **const** uint8_t *sig*[], size_t *sig_len*)
Verify if the signature provided matches with the message provided as calls to `botan_pk_op_verify_update`.

32.21 Key Agreement

typedef opaque ***botan_pk_op_ka_t**
An opaque data type for a key agreement operation. Don't mess with it.

int **botan_pk_op_key_agreement_create**(*botan_pk_op_ka_t* **op*, *botan_privkey_t key*, **const** char **kdf*, uint32_t *flags*)

int **botan_pk_op_key_agreement_destroy**(*botan_pk_op_ka_t op*)

int **botan_pk_op_key_agreement_export_public**(*botan_privkey_t key*, uint8_t *out*[], size_t **out_len*)

int **botan_pk_op_key_agreement**(*botan_pk_op_ka_t op*, uint8_t *out*[], size_t **out_len*, **const** uint8_t *other_key*[], size_t *other_key_len*, **const** uint8_t *salt*[], size_t *salt_len*)

int **botan_mceies_encrypt**(*botan_pubkey_t mce_key*, *botan_rng_t rng*, **const** char **aead*, **const** uint8_t *pt*[], size_t *pt_len*, **const** uint8_t *ad*[], size_t *ad_len*, uint8_t *ct*[], size_t **ct_len*)

int **botan_mceies_decrypt**(*botan_privkey_t mce_key*, **const** char **aead*, **const** uint8_t *ct*[], size_t *ct_len*, **const** uint8_t *ad*[], size_t *ad_len*, uint8_t *pt*[], size_t **pt_len*)

32.22 X.509 Certificates

typedef opaque ***botan_x509_cert_t**
An opaque data type for an X.509 certificate. Don't mess with it.

int **botan_x509_cert_load**(*botan_x509_cert_t* **cert_obj*, **const** uint8_t *cert*[], size_t *cert_len*)
Load a certificate from the DER or PEM representation

int **botan_x509_cert_load_file**(*botan_x509_cert_t* *cert_obj, **const** char *filename)
Load a certificate from a file.

int **botan_x509_cert_dup**(*botan_x509_cert_t* *cert_obj, *botan_x509_cert_t* cert)
Create a new object that refers to the same certificate.

int **botan_x509_cert_destroy**(*botan_x509_cert_t* cert)
Destroy the certificate object

int **botan_x509_cert_gen_selfsigned**(*botan_x509_cert_t* *cert, *botan_privkey_t* key, *botan_rng_t* rng, **const** char *common_name, **const** char *org_name)

int **botan_x509_cert_get_time_starts**(*botan_x509_cert_t* cert, char out[], size_t *out_len)
Return the time the certificate becomes valid, as a string in form "YYYYMMDDHHMMSSZ" where Z is a literal character reflecting that this time is relative to UTC. Prefer `botan_x509_cert_not_before`.

int **botan_x509_cert_get_time_expires**(*botan_x509_cert_t* cert, char out[], size_t *out_len)
Return the time the certificate expires, as a string in form "YYYYMMDDHHMMSSZ" where Z is a literal character reflecting that this time is relative to UTC. Prefer `botan_x509_cert_not_after`.

int **botan_x509_cert_not_before**(*botan_x509_cert_t* cert, uint64_t *time_since_epoch)
Return the time the certificate becomes valid, as seconds since epoch.

int **botan_x509_cert_not_after**(*botan_x509_cert_t* cert, uint64_t *time_since_epoch)
Return the time the certificate expires, as seconds since epoch.

int **botan_x509_cert_get_fingerprint**(*botan_x509_cert_t* cert, **const** char *hash, uint8_t out[], size_t *out_len)

int **botan_x509_cert_get_serial_number**(*botan_x509_cert_t* cert, uint8_t out[], size_t *out_len)
Return the serial number of the certificate.

int **botan_x509_cert_get_authority_key_id**(*botan_x509_cert_t* cert, uint8_t out[], size_t *out_len)
Return the authority key ID set in the certificate, which may be empty.

int **botan_x509_cert_get_subject_key_id**(*botan_x509_cert_t* cert, uint8_t out[], size_t *out_len)
Return the subject key ID set in the certificate, which may be empty.

int **botan_x509_cert_get_public_key_bits**(*botan_x509_cert_t* cert, uint8_t out[], size_t *out_len)
Get the serialized representation of the public key included in this certificate

int **botan_x509_cert_get_public_key**(*botan_x509_cert_t* cert, *botan_pubkey_t* *key)
Get the public key included in this certificate as a newly allocated object

int **botan_x509_cert_get_issuer_dn**(*botan_x509_cert_t* cert, **const** char *key, size_t index, uint8_t out[], size_t *out_len)
Get a value from the issuer DN field.

int **botan_x509_cert_get_subject_dn**(*botan_x509_cert_t* cert, **const** char *key, size_t index, uint8_t out[], size_t *out_len)
Get a value from the subject DN field.

int **botan_x509_cert_to_string**(*botan_x509_cert_t* cert, char out[], size_t *out_len)
Format the certificate as a free-form string.

enum botan_x509_cert_key_constraints
Certificate key usage constraints. Allowed values: *NO_CONSTRAINTS*, *DIGITAL_SIGNATURE*, *NON_REPUDIATION*, *KEY_ENCIPHERMENT*, *DATA_ENCIPHERMENT*, *KEY_AGREEMENT*, *KEY_CERT_SIGN*, *CRL_SIGN*, *ENCIPHER_ONLY*, *DECIPHER_ONLY*.

int **botan_x509_cert_allowed_usage**(*botan_x509_cert_t* cert, unsigned int key_usage)

int **botan_x509_cert_verify**(int **validation_result*, *botan_x509_cert_t* *cert*, **const** *botan_x509_cert_t* **intermediates*, size_t *intermediates_len*, **const** *botan_x509_cert_t* **trusted*, size_t *trusted_len*, **const** char **trusted_path*, size_t *required_strength*, **const** char **hostname*, uint64_t *reference_time*)

Verify a certificate. Returns 0 if validation was successful, 1 if unsuccessful, or negative on error.

Sets `validation_result` to a code that provides more information.

If not needed, set `intermediates` to NULL and `intermediates_len` to zero.

If not needed, set `trusted` to NULL and `trusted_len` to zero.

The `trusted_path` refers to a directory where one or more trusted CA certificates are stored. It may be NULL if not needed.

Set `required_strength` to indicate the minimum key and hash strength that is allowed. For instance setting to 80 allows 1024-bit RSA and SHA-1. Setting to 110 requires 2048-bit RSA and SHA-256 or higher. Set to zero to accept a default.

Set `reference_time` to be the time which the certificate chain is validated against. Use zero to use the current system clock.

const char ***botan_x509_cert_validation_status**(int *code*)

Return a (statically allocated) string associated with the verification result.

CHAPTER

THIRTYTHREE

PYTHON BINDING

New in version 1.11.14. The Python binding is based on the *ffi* module of botan and the *ctypes* module of the Python standard library.

Starting in 2.8, the class names were renamed to match Python standard conventions. However aliases are defined which allow older code to continue to work; the older names are mentioned as "previously X".

33.1 Versioning

`botan.`**`version_major`**`()`
Returns the major number of the library version.

`botan.`**`version_minor`**`()`
Returns the minor number of the library version.

`botan.`**`version_patch`**`()`
Returns the patch number of the library version.

`botan.`**`version_string`**`()`
Returns a free form version string for the library

33.2 Random Number Generators

`class` `botan.`**`RandomNumberGenerator`**`(`*rng_type = 'system'*`)`

Previously `rng`

Type 'user' also allowed (userspace HKDF RNG seeded from system rng). The system RNG is very cheap to create, as just a single file handle or CSP handle is kept open, from first use until shutdown, no matter how many 'system' rng instances are created. Thus it is easy to use the RNG in a one-off way, with *botan.rng().get(32)*.

`get``(`*length*`)`
Return some bits

`reseed``(`*bits = 256*`)`
Meaningless on system RNG, on userspace RNG causes a reseed/rekey

`reseed_from_rng``(`*source_rng*, *bits = 256*`)`
Take bits from the source RNG and use it to seed `self`

`add_entropy``(`*seed*`)`
Add some unpredictable seed data to the RNG

33.3 Hash Functions

class botan.**HashFunction**(*algo*)
Previously hash_function

Algo is a string (eg 'SHA-1', 'SHA-384', 'Skein-512')

algo_name()
Returns the name of this algorithm

clear()
Clear state

output_length()
Return output length in bytes

update(*x*)
Add some input

final()
Returns the hash of all input provided, resets for another message.

33.4 Message Authentication Codes

class botan.**MsgAuthCode**(*algo*)
Previously message_authentication_code

Algo is a string (eg 'HMAC(SHA-256)', 'Poly1305', 'CMAC(AES-256)')

algo_name()
Returns the name of this algorithm

clear()
Clear internal state including the key

output_length()
Return the output length in bytes

set_key(*key*)
Set the key

update(*x*)
Add some input

final()
Returns the MAC of all input provided, resets for another message with the same key.

33.5 Ciphers

class botan.**SymmetricCipher**(*object*, *algo*, *encrypt* = *True*)

Previously cipher

The algorithm is spcified as a string (eg 'AES-128/GCM', 'Serpent/OCB(12)', 'Threefish-512/EAX').

Set the second param to False for decryption

algo_name()
Returns the name of this algorithm

tag_length()
Returns the tag length (0 for unauthenticated modes)

default_nonce_length()
Returns default nonce length

update_granularity()
Returns update block size. Call to update() must provide input of exactly this many bytes

is_authenticated()
Returns True if this is an AEAD mode

valid_nonce_length(*nonce_len*)
Returns True if nonce_len is a valid nonce len for this mode

clear()
Resets all state

set_key(*key*)
Set the key

set_assoc_data(*ad*)
Sets the associated data. Fails if this is not an AEAD mode

start(*nonce*)
Start processing a message using nonce

update(*txt*)
Consumes input text and returns output. Input text must be of update_granularity() length. Alternately, always call finish with the entire message, avoiding calls to update entirely

finish(*txt = None*)
Finish processing (with an optional final input). May throw if message authentication checks fail, in which case all plaintext previously processed must be discarded. You may call finish() with the entire message

33.6 Bcrypt

botan.**bcrypt**(*passwd*, *rng*, *work_factor = 10*)
Provided the password and an RNG object, returns a bcrypt string

botan.**check_bcrypt**(*passwd*, *bcrypt*)
Check a bcrypt hash against the provided password, returning True iff the password matches.

33.7 PBKDF

botan.**pbkdf**(*algo*, *password*, *out_len*, *iterations = 100000*, *salt = None*)
Runs a PBKDF2 algo specified as a string (eg 'PBKDF2(SHA-256)', 'PBKDF2(CMAC(Blowfish))'). Runs with specified iterations, with meaning depending on the algorithm. The salt can be provided or otherwise is randomly chosen. In any case it is returned from the call.

Returns out_len bytes of output (or potentially less depending on the algorithm and the size of the request).

Returns tuple of salt, iterations, and psk

botan.**pbkdf_timed**(*algo*, *password*, *out_len*, *ms_to_run = 300*, *salt = rng().get(12)*)
Runs for as many iterations as needed to consumed ms_to_run milliseconds on whatever we're running on. Returns tuple of salt, iterations, and psk

33.8 Scrypt

New in version 2.8.0.

botan.**scrypt**(*out_len*, *password*, *salt*, *N=1024*, *r=8*, *p=8*)
Runs Scrypt key derivation function over the specified password and salt using Scrypt parameters N, r, p.

33.9 KDF

botan.**kdf**(*algo*, *secret*, *out_len*, *salt*)
Performs a key derviation function (such as "HKDF(SHA-384)") over the provided secret and salt values. Returns a value of the specified length.

33.10 Public Key

class botan.**PublicKey**(*object*)
Previously `public_key`

fingerprint(*hash = 'SHA-256'*)
Returns a hash of the public key

algo_name()
Returns the algorithm name

estimated_strength()
Returns the estimated strength of this key against known attacks (NFS, Pollard's rho, etc)

encoding(*pem=False*)
Returns the encoding of the key, PEM if set otherwise DER

33.11 Private Key

class botan.**PrivateKey**(*algo*, *param*, *rng*)
Previously `private_key`

Constructor creates a new private key. The parameter type/value depends on the algorithm. For "rsa" is is the size of the key in bits. For "ecdsa" and "ecdh" it is a group name (for instance "secp256r1"). For "ecdh" there is also a special case for group "curve25519" (which is actually a completely distinct key type with a non-standard encoding).

get_public_key()

Return a public_key object

export()

33.12 Public Key Operations

class botan.**PKEncrypt**(*pubkey*, *padding*)
Previously pk_op_encrypt

encrypt(*msg*, *rng*)

class botan.**PKDecrypt**(*privkey*, *padding*)
Previously pk_op_decrypt

decrypt(*msg*)

class botan.**PKSign**(*privkey*, *hash_w_padding*)
Previously pk_op_sign

update(*msg*)

finish(*rng*)

class botan.**PKVerify**(*pubkey*, *hash_w_padding*)
Previously pk_op_verify

update(*msg*)

check_signature(*signature*)

class botan.**PKKeyAgreement**(*privkey*, *kdf*)
Previously pk_op_key_agreement

public_value()

Returns the public value to be passed to the other party

agree(*other*, *key_len*, *salt*)

Returns a key derived by the KDF.

33.13 Multiple Precision Integers (MPI)

New in version 2.8.0.

class botan.**MPI**(*initial_value=None*)
Initialize an MPI object with specified value, left as zero otherwise. The initial_value should be an int, str, or MPI.

Most of the usual arithmetic operators (__add__, __mul__, etc) are defined.

inverse_mod(*modulus*)
Return the inverse of self modulo modulus, or zero if no inverse exists

is_prime(*rng*, *prob=128*)
Test if self is prime

pow_mod(exponent, modulus):
Return self to the exponent power modulo modulus

33.14 Format Preserving Encryption (FE1 scheme)

New in version 2.8.0.

class botan.**FormatPreservingEncryptionFE1**(*modulus*, *key*, *rounds=5*, *compat_mode=False*)
Initialize an instance for format preserving encryption

encrypt(*msg*, *tweak*)
The msg should be a botan2.MPI or an object which can be converted to one

decrypt(*msg*, *tweak*)
The msg should be a botan2.MPI or an object which can be converted to one

33.15 HOTP

New in version 2.8.0.

class botan.**HOTP**(*key*, *hash="SHA-1"*, *digits=6*)

generate(*counter*)
Generate an HOTP code for the provided counter

check(*code*, *counter*, *resync_range=0*)
Check if provided `code` is the correct code for `counter`. If `resync_range` is greater than zero, HOTP also checks up to `resync_range` following counter values.

Returns a tuple of (bool,int) where the boolean indicates if the code was valid, and the int indicates the next counter value that should be used. If the code did not verify, the next counter value is always identical to the counter that was passed in. If the code did verify and resync_range was zero, then the next counter will always be counter+1.

CHAPTER

THIRTYFOUR

COMMAND LINE INTERFACE

34.1 Outline

The `botan` program is a command line tool for using a broad variety of functions of the Botan library in the shell.

All commands follow the syntax `botan <command> <command-options>`.

If `botan` is run with an unknown command, or without any command, or with the `--help` option, all available commands will be printed. If a particular command is run with the `--help` option (like `botan <command> --help`) some information about the usage of the command is printed.

34.2 Hash Function

`hash --algo=SHA-256 --buf-size=4096 --no-fsname files` Compute the *algo* digest over the data in any number of *files*. If no files are listed on the command line, the input source defaults to standard input. Unless the `--no-fsname` option is given, the filename is printed alongside the hash, in the style of tools such as `sha256sum`.

34.3 Password Hash

`gen_bcrypt --work-factor=12 password` Calculate the bcrypt password digest of *password*. *work-factor* is an integer between 4 and 18. A higher *work-factor* value results in a more expensive hash calculation.

`check_bcrypt password hash` Checks if the bcrypt hash of the passed *password* equals the passed *hash* value.

34.4 HMAC

`hmac --hash=SHA-256 --buf-size=4096 --no-fsname key files` Compute the HMAC tag with the cryptographic hash function *hash* using the key in file *key* over the data in *files*. *files* defaults to STDIN. Unless the `--no-fsname` option is given, the filename is printed alongside the HMAC value.

34.5 Public Key Cryptography

`keygen --algo=RSA --params= --passphrase= --pbe= --pbe-millis=300 --der-out`
Generate a PKCS #8 *algo* private key. If *der-out* is passed, the pair is BER encoded. Otherwise, PEM encoding

is used. To protect the PKCS #8 formatted key, it is recommended to encrypt it with a provided *passphrase*. *pbe* is the name of the desired encryption algorithm, which uses *pbe-millis* milliseconds to derive the encryption key from the passed *passphrase*. Algorithm specific parameters, as the desired bit length of an RSA key, can be passed with *params*.

- For RSA *params* specifies the bit length of the RSA modulus. It defaults to 3072.
- For DH *params* specifies the DH parameters. It defaults to modp/ietf/2048.
- For DSA *params* specifies the DSA parameters. It defaults to dsa/botan/2048.
- For EC algorithms *params* specifies the elliptic curve. It defaults to secp256r1.

The default *pbe* algorithm is "PBES2(AES-256/CBC,SHA-256)".

With PBES2 scheme, you can select any CBC or GCM mode cipher which has an OID defined (such as 3DES, Camellia, SM4, Twofish or Serpent). However most other implementations support only AES or 3DES in CBC mode. You can also choose Scrypt instead of PBKDF2, by using "Scrypt" instead of the name of a hash function, for example "PBES2(AES-256/CBC,Scrypt)"

pkcs8 --pass-in= --pub-out --der-out --pass-out= --pbe= --pbe-millis=300 key Open a PKCS #8 formatted key at *key*. If *key* is encrypted, the passphrase must be passed as *pass-in*. It is possible to (re)encrypt the read key with the passphrase passed as *pass-out*. The parameters *pbe-millis* and *pbe* work similarly to `keygen`.

sign --der-format --passphrase= --hash=SHA-256 --emsa= key file Sign the data in *file* using the PKCS #8 private key *key*. If *key* is encrypted, the used passphrase must be passed as *pass-in*. *emsa* specifies the signature scheme and *hash* the cryptographic hash function used in the scheme.

- For RSA signatures EMSA4 (RSA-PSS) is the default scheme.
- For ECDSA and DSA *emsa* defaults to EMSA1 (signing the hash directly)

For ECDSA and DSA, the option `--der-format` outputs the signature as an ASN.1 encoded blob. Some other tools (including `openssl`) default to this format.

verify --der-format --hash=SHA-256 --emsa= pubkey file signature Verify the authenticity of the data in *file* with the provided signature *signature* and the public key *pubkey*. Similarly to the signing process, *emsa* specifies the signature scheme and *hash* the cryptographic hash function used in the scheme.

gen_dl_group --pbits=1024 --qbits=0 --seed= --type=subgroup Generate ANSI X9.42 encoded Diffie-Hellman group parameters.

- If *type=subgroup* is passed, the size of the prime subgroup q is sampled as a prime of *qbits* length and p is *pbits* long. If *qbits* is not passed, its length is estimated from *pbits* as described in RFC 3766.
- If *type=strong* is passed, p is sampled as a safe prime with length *pbits* and the prime subgroup has size q with *pbits*-1 length.
- If *type=dsa* is used, p and q are generated by the algorithm specified in FIPS 186-4. If the `--seed` parameter is used, it allows to select the seed value, instead of one being randomly generated. If the seed does not in fact generate a valid DSA group, the command will fail.

dl_group_info --pem name Print raw Diffie-Hellman parameters (p,g) of the standardized DH group *name*. If *pem* is set, the X9.42 encoded group is printed.

ec_group_info --pem name Print raw elliptic curve domain parameters of the standardized curve *name*. If *pem* is set, the encoded domain is printed.

pk_encrypt --aead=AES-256/GCM rsa_pubkey datafile Encrypts `datafile` using the specified AEAD algorithm, under a key protected by the specified RSA public key.

pk_decrypt rsa_privkey datafile Decrypts a file encrypted with `pk_encrypt`. If the key is encrypted using a password, it will be prompted for on the terminal.

34.6 X.509

gen_pkcs10 key CN --country= --organization= --email= --key-pass= --hash=SHA-256 --emsa=
Generate a PKCS #10 certificate signing request (CSR) using the passed PKCS #8 private key *key*. If the private key is encrypted, the decryption passphrase *key-pass* has to be passed.*emsa* specifies the padding scheme to be used when calculating the signature.

- For RSA keys EMSA4 (RSA-PSS) is the default scheme.
- For ECDSA, DSA, ECGDSA, ECKCDSA and GOST-34.10 keys *emsa* defaults to EMSA1.

gen_self_signed key CN --country= --dns= --organization= --email= --key-pass= --ca --hash=
Generate a self signed X.509 certificate using the PKCS #8 private key *key*. If the private key is encrypted, the decryption passphrase *key-pass* has to be passed. If *ca* is passed, the certificate is marked for certificate authority (CA) usage. *emsa* specifies the padding scheme to be used when calculating the signature.

- For RSA keys EMSA4 (RSA-PSS) is the default scheme.
- For ECDSA, DSA, ECGDSA, ECKCDSA and GOST-34.10 keys *emsa* defaults to EMSA1.

sign_cert --ca-key-pass= --hash=SHA-256 --duration=365 --emsa= ca_cert ca_key pkcs10_req
Create a CA signed X.509 certificate from the information contained in the PKCS #10 CSR *pkcs10_req*. The CA certificate is passed as *ca_cert* and the respective PKCS #8 private key as *ca_key*. If the private key is encrypted, the decryption passphrase *ca-key-pass* has to be passed. The created certificate has a validity period of *duration* days. *emsa* specifies the padding scheme to be used when calculating the signature. *emsa* defaults to the padding scheme used in the CA certificate.

ocsp_check subject issuer Verify an X.509 certificate against the issuers OCSP responder. Pass the certificate to validate as *subject* and the CA certificate as *issuer*.

cert_info --fingerprint --ber file Parse X.509 PEM certificate and display data fields. If `--fingerprint` is used, the certificate's fingerprint is also printed.

cert_verify subject *ca_certs Verify if the provided X.509 certificate *subject* can be successfully validated. The list of trusted CA certificates is passed with *ca_certs*, which is a list of one or more certificates.

34.7 TLS Server/Client

tls_ciphers --policy=default --version=tls1.2 Prints the list of ciphersuites that will be offered under a particular policy/version. The policy can be any of the the strings "default", "suiteb_128", "suiteb_192", "strict", or "all" to denote built-in policies, or it can name a file from which a policy description will be read.

tls_client host --port=443 --print-certs --policy= --tls1.0 --tls1.1 --tls1.2 --session-db=
Implements a testing TLS client, which connects to *host* via TCP or UDP on port *port*. The TLS version can be set with the flags *tls1.0*, *tls1.1* and *tls1.2* of which the lowest specified version is automatically chosen. If none of the TLS version flags is set, the latest supported version is chosen. The client honors the TLS policy defined in the *policy* file and prints all certificates in the chain, if *print-certs* is passed. *next-protocols* is a comma separated list and specifies the protocols to advertise with Application-Layer Protocol Negotiation (ALPN).

tls_server cert key --port=443 --type=tcp --policy= Implements a testing TLS server, which allows TLS clients to connect. Binds to either TCP or UDP on port *port*. The server uses the certificate *cert* and the respective PKCS #8 private key *key*. The server honors the TLS policy defined in the *policy* file.

tls_http_server cert key --port=443 --policy= --session-db --session-db-pass=
Only available if Boost.Asio support was enabled. Provides a simple HTTP server which replies to all requests with an informational text output. The server honors the TLS policy defined in the *policy* file.

tls_proxy listen_port target_host target_port server_cert server_key Only available if Boost.Asio support was enabled. Listens on a port and forwards all connects to a target server specified at `target_host` and `target_port`.

34.8 Number Theory

is_prime --prob=56 n Test if the integer *n* is composite or prime with a Miller-Rabin primality test with *(prob+2)/2* iterations.

factor n Factor the integer *n* using a combination of trial division by small primes, and Pollard's Rho algorithm. It can in reasonable time factor integers up to 110 bits or so.

gen_prime --count=1 bits Samples *count* primes with a length of *bits* bits.

34.9 PSK Database

The PSK database commands are only available if sqlite3 support was compiled in.

psk_set db db_key name psk Using the PSK database named db and encrypting under the (hex) key `db_key`, save the provided psk (also hex) under `name`:

```
$ botan psk_set psk.db deadba55 bunny f00fee
```

psk_get db db_key name Get back a value saved with `psk_set`:

```
$ botan psk_get psk.db deadba55 bunny
f00fee
```

psk_list db db_key List all values saved to the database under the given key:

```
$ botan psk_list psk.db deadba55
bunny
```

34.10 Data Encoding/Decoding

base64_dec file Encode *file* to Base64.

base64_enc file Decode Base64 encoded *file*.

hex_dec file Encode *file* to Hex.

hex_enc file Decode Hex encoded *file*.

34.11 Miscellaneous Commands

version --full Print the version number. If option `--full` is provided, additional details are printed.

config info_type Prints build information, useful for applications which want to build against the library. The `info_type` argument can be any of `prefix`, `cflags`, `ldflags`, or `libs`. This is similar to information provided by the `pkg-config` tool.

cpuid List available processor flags (aes_ni, SIMD extensions, ...).

asn1print file Decode and print *file* with ASN.1 Basic Encoding Rules (BER).

http_get url Retrieve resource from the passed http *url*.

speed --msec=500 --provider= --buf-size=1024 algos Measures the speed of the passed *algos*. If no *algos* are passed all available speed tests are executed. *msec* (in milliseconds) sets the period of measurement for each algorithm. The *buf-size* option allows testing the same algorithm on one or more input sizes, for example `speed --buf-size=136,1500 AES-128/GCM` tests the performance of GCM for small and large packet sizes.

rng --system --rdrand bytes Sample *bytes* random bytes from the specified random number generator. If *system* is set, the system RNG is used. If *system* is unset and *rdrand* is set, the hardware RDRAND instruction is used if available. If both are unset, HMAC_DRBG is used.

cc_encrypt CC passphrase --tweak= Encrypt the passed valid credit card number *CC* using FPE encryption and the passphrase *passphrase*. The key is derived from the passphrase using PBKDF2 with SHA256. Due to the nature of FPE, the ciphertext is also a credit card number with a valid checksum. *tweak* is public and parameterizes the encryption function.

cc_decrypt CC passphrase --tweak= Decrypt the passed valid ciphertext *CC* using FPE decryption with the passphrase *passphrase* and the tweak *tweak*.

CHAPTER

THIRTYFIVE

SIDE CHANNELS

Many cryptographic systems can be easily broken by side channels. This document notes side channel protections which are currently implemented, as well as areas of the code which are known to be vulnerable to side channels. The latter are obviously all open for future improvement.

The following text assumes the reader is already familiar with cryptographic implementations, side channel attacks, and common countermeasures.

35.1 RSA

Blinding is always used to protect private key operations (there is no way to turn it off). Both base blinding and exponent blinding are used.

For base blinding, as an optimization, instead of choosing a new random mask and inverse with each decryption, both the mask and its inverse are simply squared to choose the next blinding factor. This is much faster than computing a fresh value each time, and the additional relation is thought to provide only minimal useful information for an attacker. Every BOTAN_BLINDING_REINIT_INTERVAL (default 64) operations, a new starting point is chosen.

Exponent blinding uses new values for each signature, with 64 bit masks.

RSA signing uses the CRT optimization, which is much faster but vulnerable to trivial fault attacks [RsaFault] which can result in the key being entirely compromised. To protect against this (or any other computational error which would have the same effect as a fault attack in this case), after every private key operation the result is checked for consistency with the public key. This introduces only slight additional overhead and blocks most fault attacks; it is possible to use a second fault attack to bypass this verification, but such a double fault attack requires significantly more control on the part of an attacker than a BellCore style attack, which is possible if any error at all occurs during either modular exponentiation involved in the RSA signature operation.

See blinding.cpp and rsa.cpp.

If the OpenSSL provider is enabled, then no explicit blinding is done; we assume OpenSSL handles this. See openssl_rsa.cpp.

35.2 Decryption of PKCS #1 v1.5 Ciphertexts

This padding scheme is used with RSA, and is very vulnerable to errors. In a scenario where an attacker can repeatedly present RSA ciphertexts, and a legitimate key holder will attempt to decrypt each ciphertext and simply indicates to the attacker if the PKCS padding was valid or not (without revealing any additional information), the attacker can use this behavior as an oracle to perform iterative decryption of arbitrary RSA ciphertexts encrypted under that key. This is the famous million message attack [MillionMsg]. A side channel such as a difference in time taken to handle valid and invalid RSA ciphertexts is enough to mount the attack [MillionMsgTiming].

Preventing this issue in full requires some application level changes. In protocols which know the expected length of the encrypted key, PK_Decryptor provides the function *decrypt_or_random* which first generates a random fake key, then decrypts the presented ciphertext, then in constant time either copies out the random key or the decrypted plaintext depending on if the ciphertext was valid or not (valid padding and expected plaintext length). Then in the case of an attack, the protocol will carry on with a randomly chosen key, which will presumably cause total failure in a way that does not allow an attacker to distinguish (via any timing or other side channel, nor any error messages specific to the one situation vs the other) if the RSA padding was valid or invalid.

One very important user of PKCS #1 v1.5 encryption is the TLS protocol. In TLS, some extra versioning information is embedded in the plaintext message, along with the key. It turns out that this version information must be treated in an identical (constant-time) way with the PKCS padding, or again the system is broken. [VersionOracle]. This is supported by a special version of PK_Decryptor::decrypt_or_random that additionally allows verifying one or more content bytes, in addition to the PKCS padding.

See eme_pkcs.cpp and pubkey.cpp.

35.3 Verification of PKCS #1 v1.5 Signatures

One way of verifying PKCS #1 v1.5 signature padding is to decode it with an ASN.1 BER parser. However such a design commonly leads to accepting signatures besides the (single) valid RSA PKCS #1 v1.5 signature for any given message, because often the BER parser accepts variations of the encoding which are actually invalid. It also needlessly exposes the BER parser to untrusted inputs.

It is safer and simpler to instead re-encode the hash value we are expecting using the PKCS #1 v1.5 encoding rules, and const time compare our expected encoding with the output of the RSA operation. So that is what Botan does.

See emsa_pkcs.cpp.

35.4 OAEP

RSA OAEP is (PKCS#1 v2) is the recommended version of RSA encoding standard, because it is not directly vulnerable to Bleichenbacher attack. However, if implemented incorrectly, a side channel can be presented to an attacker and create an oracle for decrypting RSA ciphertexts [OaepTiming].

This attack is avoided in Botan by making the OAEP decoding operation run without any conditional jumps or indexes, with the only variance in runtime coming from the length of the RSA key (which is public information).

See eme_oaep.cpp.

35.5 Modular Exponentiation

Modular exponentiation uses a fixed window algorithm with Montgomery representation. A side channel silent table lookup is used to access the precomputed powers. The caller provides the maximum possible bit length of the exponent, and the exponent is zero-padded as required. For example, in a DSA signature with 256-bit q, the caller will specify a maximum length of exponent of 256 bits, even if the k that was generated was 250 bits. This avoids leaking the length of the exponent through the number of loop iterations. See monty_exp.cpp and monty.cpp

Karatsuba multiplication algorithm avoids any conditional branches; in cases where different operations must be performed it instead uses masked operations. See mp_karat.cpp for details.

The Montgomery reduction is written (and tested) to run in constant time. The final reduction is handled with a masked subtraction. See mp_monty.cpp.

35.6 Barrett Reduction

The Barrett reduction code is written to avoid input dependent branches. However the Barrett algorithm only works for inputs that are most the square of the modulus; larger values fall back to the schoolbook division algorithm which is not const time.

35.7 ECC point decoding

The API function OS2ECP, which is used to convert byte strings to ECC points, verifies that all points satisfy the ECC curve equation. Points that do not satisfy the equation are invalid, and can sometimes be used to break protocols ([InvalidCurve] [InvalidCurveTLS]). See point_gfp.cpp.

35.8 ECC scalar multiply

There are several different implementations of ECC scalar multiplications which depend on the API invoked. This include `PointGFp::operator*`, `EC_Group::blinded_base_point_multiply` and `EC_Group::blinded_var_point_multiply`.

The `PointGFp::operator*` implementation uses the Montgomery ladder, which is fairly resistant to side channels. However it leaks the size of the scalar, because the loop iterations are bounded by the scalar size. It should not be used in cases when the scalar is a secret.

Both `blinded_base_point_multiply` and `blinded_var_point_multiply` apply side channel countermeasures. The scalar is masked by a multiple of the group order (this is commonly called Coron's first countermeasure [CoronDpa]), currently the mask is an 80 bit random value.

Botan stores all ECC points in Jacobian representation. This form allows faster computation by representing points (x,y) as (X,Y,Z) where x=X/Z^2 and y=Y/Z^3. As the representation is redundant, for any randomly chosen non-zero r, (X*r^2,Y*r^3,Z*r) is an equivalent point. Changing the point values prevents an attacker from mounting attacks based on the input point remaining unchanged over multiple executions. This is commonly called Coron's third countermeasure, see again [CoronDpa].

The base point multiplication algorithm is a comb-like technique which precomputes `P^i,(2*P)^i,(3*P)^i` for all `i` in the range of valid scalars. This means the scalar multiplication involves only point additions and no doublings, which may help against attacks which rely on distinguishing between point doublings and point additions. The elements of the table are accessed by masked lookups, so as not to leak information about bits of the scalar via a cache side channel.

The variable point multiplication algorithm uses a fixed-window algorithm. Since this is normally invoked using untrusted points (eg during ECDH key exchange) it randomizes all inputs to prevent attacks which are based on chosen input points. The table of precomputed multiples is accessed using a masked lookup which should not leak information about the secret scalar to an attacker who can mount a cache-based side channel attack.

See point_gfp.cpp and point_mul.cpp

35.9 ECDH

ECDH verifies (through its use of OS2ECP) that all input points received from the other party satisfy the curve equation. This prevents twist attacks. The same check is performed on the output point, which helps prevent fault attacks.

35.10 ECDSA

Inversion of the ECDSA nonce k must be done in constant time, as any leak of even a single bit of the nonce can be sufficient to allow recovering the private key. In Botan all inverses modulo an odd number are performed using a constant time algorithm due to Niels Möller.

35.11 x25519

The x25519 code is independent of the main Weierstrass form ECC code, instead based on curve25519-donna-c64.c by Adam Langley. The code seems immune to cache based side channels. It does make use of integer multiplications; on some old CPUs these multiplications take variable time and might allow a side channel attack. This is not considered a problem on modern processors.

35.12 TLS CBC ciphersuites

The original TLS v1.0 CBC Mac-then-Encrypt mode is vulnerable to an oracle attack. If an attacker can distinguish padding errors through different error messages [TlsCbcOracle] or via a side channel attack like [Lucky13], they can abuse the server as a decryption oracle.

The side channel protection for Lucky13 follows the approach proposed in the Lucky13 paper. It is not perfectly constant time, but does hide the padding oracle in practice. Tools to test TLS CBC decoding are included in the timing tests. See https://github.com/randombit/botan/pull/675 for more information.

The Encrypt-then-MAC extension, which completely avoids the side channel, is implemented and used by default for CBC ciphersuites.

35.13 CBC mode padding

In theory, any good protocol protects CBC ciphertexts with a MAC. But in practice, some protocols are not good and cannot be fixed immediately. To avoid making a bad problem worse, the code to handle decoding CBC ciphertext padding bytes runs in constant time, depending only on the block size of the cipher.

35.14 AES

Some x86, ARMv8 and POWER processors support AES instructions which are fast and are thought to be side channel silent. These instructions are used when available.

On x86 processors without AES-NI but with SSSE3 (which includes older Intel Atoms and Core2 Duos, and even now some embedded or low power x86 chips), a version of AES using pshufb is used which is both fast and side channel silent. It is based on code by Mike Hamburg [VectorAes], see aes_ssse3.cpp. This same technique could be applied with NEON or AltiVec, and the paper suggests some optimizations for the AltiVec shuffle.

On all other processors, a table lookup version (T-tables) is used. This approach is relatively fast, but known to be very vulnerable to side channels. To reduce the side channel signature, AES uses only 1K of tables (instead of 4 1K tables which is typical). The tables are computed at runtime which prevents an attacker from performing a Flush+Reload attack since the address of the tables is not fixed. Before each encryption/decryption operation, a value from each cache line of the T-table is read to compute a volatile value Z. This Z value is computed in such a way that it is always zero. Since the T-table itself is computed at runtime, it *should* be difficult for a compiler to deduce this fact. Then the Z value is xor'ed into the input block, preventing the compiler from eliding it. It is almost certain that this

implementation is still vulnerable to a side channel attack; all these countermeasures do is increase the cost (in terms of samples required or analysis time) of an attack.

If using AES in an environment where side channels are a concern and hardware instructions are not available, prefer AES-256. In the case of AES, a larger key increases the cost of (*but does not prevent*) side channel attacks based on cache usage. The paper [Aes256Sc] suggests it increase the samples required by a factor of roughly 6, though this analysis assumes a dedicated T4 table is used in the last round, an implementation technique Botan avoids precisely because such a table is notorious for leaking information.

The Botan block cipher API already supports bitslicing implementations, so a const time 8x bitsliced AES could be integrated fairly easily.

35.15 GCM

On platforms that support a carryless multiply instruction (ARMv8 and recent x86), GCM is fast and constant time.

On all other platforms, GCM uses an algorithm based on precomputing all powers of H from 1 to 128. Then for every bit of the input a mask is formed which allows conditionally adding that power without leaking information via a cache side channel. There is also an SSSE3 variant of this algorithm which is somewhat faster on processors which have SSSE3 but no AES-NI instructions.

35.16 OCB

It is straightforward to implement OCB mode in a efficient way that does not depend on any secret branches or lookups. See ocb.cpp for the implementation.

35.17 Poly1305

The Poly1305 implementation does not have any secret lookups or conditionals. The code is based on the public domain version by Andrew Moon.

35.18 DES/3DES

The DES implementation uses table lookups, and is likely vulnerable to side channel attacks. DES or 3DES should be avoided in new systems. The proper fix would be a scalar bitsliced implementation, this is not seen as worth the engineering investment given these algorithms end of life status.

35.19 Twofish

This algorithm uses table lookups with secret sboxes. No cache-based side channel attack on Twofish has ever been published, but it is possible nobody sufficiently skilled has ever tried.

35.20 ChaCha20, Serpent, Threefish, ...

Some algorithms including ChaCha, Salsa, Serpent and Threefish are 'naturally' silent to cache and timing side channels on all recent processors.

35.21 IDEA

IDEA encryption, decryption, and key schedule are implemented to take constant time regardless of their inputs.

35.22 Hash Functions

Most hash functions included in Botan such as MD5, SHA-1, SHA-2, SHA-3, Skein, and BLAKE2 do not require any input-dependent memory lookups, and so seem to not be affected by common CPU side channels.

35.23 Memory comparisons

The function same_mem in header mem_ops.h provides a constant-time comparison function. It is used when comparing MACs or other secret values. It is also exposed for application use.

35.24 Memory zeroizing

There is no way in portable C/C++ to zero out an array before freeing it, in such a way that it is guaranteed that the compiler will not elide the 'additional' (seemingly unnecessary) writes to zero out the memory.

The function secure_scrub_memory (in mem_ops.cpp) uses some system specific trick to zero out an array. On Windows it uses the directly supported API function RtlSecureZeroMemory.

On other platforms, by default the trick of referencing memset through a volatile function pointer is used. This approach is not guaranteed to work on all platforms, and currently there is no systematic check of the resulting binary function that it is compiled as expected. But, it is the best approach currently known and has been verified to work as expected on common platforms.

If BOTAN_USE_VOLATILE_MEMSET_FOR_ZERO is set to 0 in build.h (not the default) a byte at a time loop through a volatile pointer is used to overwrite the array.

35.25 Memory allocation

Botan's secure_vector type is a std::vector with a custom allocator. The allocator calls secure_scrub_memory before freeing memory.

Some operating systems support an API call to lock a range of pages into memory, such that they will never be swapped out (mlock on POSIX, VirtualLock on Windows). On many POSIX systems mlock is only usable by root, but on Linux, FreeBSD and possibly other systems a small amount of memory can be mlock'ed by processes without extra credentials.

If available, Botan uses such a region for storing key material. It is created in anonymous mapped memory (not disk backed), locked in memory, and scrubbed on free. This memory pool is used by secure_vector when available. It can be disabled at runtime setting the environment variable BOTAN_MLOCK_POOL_SIZE to 0.

35.26 Automated Analysis

Currently the main tool used by the Botan developers for testing for side channels at runtime is valgrind; valgrind's runtime API is used to taint memory values, and any jumps or indexes using data derived from these values will cause a valgrind warning. This technique was first used by Adam Langley in ctgrind. See header ct_utils.h.

To check, install valgrind, configure the build with –with-valgrind, and run the tests.

There is also a test utility built into the command line util, *timing_test*, which runs an operation on several different inputs many times in order to detect simple timing differences. The output can be processed using the Mona timing report library (https://github.com/seecurity/mona-timing-report). To run a timing report (here for example pow_mod):

```
$ ./botan timing_test pow_mod > pow_mod.raw
```

This must be run from a checkout of the source, or otherwise `--test-data-dir=` must be used to point to the expected input files.

Build and run the Mona report as:

```
$ git clone https://github.com/seecurity/mona-timing-report.git
$ cd mona-timing-report
$ ant
$ java -jar ReportingTool.jar --lowerBound=0.4 --upperBound=0.5 --inputFile=pow_mod.
↪raw --name=PowMod
```

This will produce plots and an HTML file in subdirectory starting with `reports_` followed by a representation of the current date and time.

NOTES FOR DISTRIBUTORS

This document has information for anyone who is packaging copies of Botan for use by downstream developers, such as through a Linux distribution or other package management system.

36.1 Recommended Options

In most environments, zlib, bzip2, and sqlite are already installed, so there is no reason to not include support for them in Botan as well. Build with options `--with-zlib --with-bzip2 --with-sqlite3` to enable these features.

36.2 Set Distribution Info

If your distribution of Botan involves creating library binaries, use the configure.py flag `--distribution-info=` to set the version of your packaging. For example Foonix OS might distribute its 4th revision of the package for Botan 2.1.3 using `--distribution-info='Foonix 2.1.3-4'`. The string is completely free-form, since it depends on how the distribution numbers releases and packages.

Any value set with `--distribution-info` flag will be included in the version string, and can read through the `BOTAN_DISTRIBUTION_INFO` macro.

36.3 Minimize Distribution Patches

We (Botan upstream) *strongly* prefer that downstream distributions maintain no long-term patches against Botan. Even if it is a build problem which probably only affects your environment, please open an issue on github and include the patch you are using. Perhaps the issue does affect other users, and even if not it would be better for everyone if the library were improved so it were not necessary for the patch to be created in the first place. For example, having to modify or remove a build data file, or edit the makefile after generation, suggests an area where the build system is insufficiently flexible.

Obviously nothing in the BSD-2 license prevents you from distributing patches or modified versions of Botan however you please. But long term patches by downstream distributors have a tendency to bitrot and sometimes even result in security problems (such as in the Debian OpenSSL RNG fiasco) because the patches are never reviewed by the library developers. So we try to discourage them, and work to ensure they are never necessary.

CHAPTER

THIRTYSEVEN

FUZZING THE LIBRARY

Botan comes with a set of fuzzing endpoints which can be used to test the library.

37.1 Fuzzing with libFuzzer

To fuzz with libFuzzer (https://llvm.org/docs/LibFuzzer.html), you'll first need to compile libFuzzer:

```
$ svn co https://llvm.org/svn/llvm-project/compiler-rt/trunk/lib/fuzzer libFuzzer
$ cd libFuzzer && clang -c -g -O2 -std=c++11 *.cpp
$ ar cr libFuzzer.a libFuzzer/*.o
```

Then build the fuzzers:

```
$ ./configure.py --cc=clang --build-fuzzer=libfuzzer --unsafe-fuzzer-mode \
      --enable-sanitizers=coverage,address,undefined
$ make fuzzers
```

Enabling 'coverage' sanitizer flags is required for libFuzzer to work. Address sanitizer and undefined sanitizer are optional.

The fuzzer binaries will be in *build/fuzzer*. Simply pick one and run it, optionally also passing a directory containing corpus inputs.

Using *libfuzzer* build mode implicitly assumes the fuzzers need to link with *libFuzzer*; if another library is needed (for example in OSS-Fuzz, which uses *libFuzzingEngine*), use the flag *–with-fuzzer-lib* to specify the desired name.

37.2 Fuzzing with AFL

To fuzz with AFL (http://lcamtuf.coredump.cx/afl/):

```
$ ./configure.py --with-sanitizers --build-fuzzer=afl --unsafe-fuzzer-mode --cc-
↪bin=afl-g++
$ make fuzzers
```

For AFL sanitizers are optional. You can also use *afl-clang-fast++* or *afl-clang++*, be sure to set *–cc=clang* also.

The fuzzer binaries will be in *build/fuzzer*. To run them you need to run under *afl-fuzz*:

```
$ afl-fuzz -i corpus_path -o output_path ./build/fuzzer/binary
```

37.3 Fuzzing with TLS-Attacker

TLS-Attacker (https://github.com/RUB-NDS/TLS-Attacker) includes a mode for fuzzing TLS servers. A prebuilt copy of TLS-Attacker is available in a git repository:

```
$ git clone --depth 1 https://github.com/randombit/botan-ci-tools.git
```

To run it against Botan's server:

```
$ ./configure.py --with-sanitizers
$ make botan
$ ./src/scripts/run_tls_attacker.py ./botan ./botan-ci-tools
```

Output and logs from the fuzzer are placed into */tmp*. See the TLS-Attacker documentation for more information about how to use this tool.

37.4 Input Corpus

AFL requires an input corpus, and libFuzzer can certainly make good use of it.

Some crypto corpus repositories include

- https://github.com/randombit/crypto-corpus
- https://github.com/mozilla/nss-fuzzing-corpus
- https://github.com/google/boringssl/tree/master/fuzz
- https://github.com/openssl/openssl/tree/master/fuzz/corpora

37.5 Adding new fuzzers

New fuzzers are created by adding a source file to *src/fuzzers* which have the signature:

```
void fuzz(const uint8_t in[], size_t len)
```

After adding your fuzzer, rerun *./configure.py* and build.

CHAPTER

THIRTYEIGHT

DEPRECATED FEATURES

The following functionality is currently deprecated, and will likely be removed in a future release. If you think you have a good reason to be using one of the following, contact the developers to explain your use case if you want to make sure your code continues to work.

This is in addition to specific API calls marked with BOTAN_DEPRECATED in the source.

- Directly accessing the member variables of types calendar_point, ASN1_Attribute, AlgorithmIdentifier, and BER_Object
- The headers `botan.h`, `init.h`, `lookup.h`, `threefish.h`, `sm2_enc.h`
- All or nothing package transform (`package.h`)
- The TLS constructors taking *std::function* for callbacks. Instead use the TLS::Callbacks interface.
- Using `X509_Certificate::subject_info` and `issuer_info` to access any information that is not included in the DN or subject alternative name. Prefer using the specific assessor functions for other data, eg instead of `cert.subject_info("X509.Certificate.serial")` use `cert.serial_number()`.
- The Buffered_Computation base class. In a future release the class will be removed, and all of member functions instead declared directly on MessageAuthenticationCode and HashFunction. So this only affects you if you are directly referencing *Botan::Buffered_Computation* in some way.
- Support for Visual C++ 2013
- Platform support for Google Native Client
- Support for PathScale and HP compilers
- TLS: 3DES and SEED ciphersuites
- TLS: Anonymous DH/ECDH ciphersuites
- TLS: DHE-PSK ciphersuites
- TLS: DSA ciphersuites/certs
- TLS: static RSA key exchange ciphersuites
- TLS: CCM_8 ciphersuites
- TLS: TLSv1.0 and v1.1, DTLS v1.0
- TLS: CBC ciphersuites
- Block ciphers CAST-256, Kasumi, MISTY1, and DESX.
- CBC-MAC
- PBKDF1 key derivation
- GCM support for 64-bit tags

- Old (Google specific) ChaCha20 TLS ciphersuites
- Weak or rarely used ECC builtin groups including "secp160k1", "secp160r1", "secp160r2", "secp192k1", "secp192r1", "secp224k1", "secp224r1", "brainpool160r1", "brainpool192r1", "brainpool224r1", "brainpool320r1", "x962_p192v2", "x962_p192v3", "x962_p239v1", "x962_p239v2", "x962_p239v3".
- All built in MODP groups < 2048 bits
- All pre-created DSA groups

CHAPTER

THIRTYNINE

ABI STABILITY

Botan uses semantic versioning for the API; if API features are added the minor version increases, whereas if API compatibility breaks occur the major version is increased.

However no guarantees about ABI are made between releases. Maintaining an ABI compatible release in a complex C++ API is exceedingly expensive in development time; just adding a single member variable or virtual function is enough to cause ABI issues.

If ABI changes, the soname revision will increase to prevent applications from linking against a potentially incompatible version at runtime.

If you are concerned about long-term ABI issues, considering using the C API instead; this subset *is* ABI stable.

You can review a report on ABI changes to Botan at https://abi-laboratory.pro/tracker/timeline/botan/

CHAPTER

FORTY

DEVELOPMENT ROADMAP

40.1 Near Term Plans

Here is an outline for the development plans over the next 12-18 months, as of November 2017.

40.1.1 TLS Hardening/Testing

Leverage TLS-Attacker better, for example using custom workflows. Add tests using BoringSSL's hacked Go TLS stack. Add interop testing with OpenSSL as part of CI. Improve fuzzer coverage.

40.1.2 Expose TLS to C89 and Python

Exposing TLS to C would allow for many new applications to make use of Botan.

40.1.3 Interface to PSK and SRP databases

Adding support for databases storing encrypted PSKs and SRP credentials. (PSK database support was added in 2.4.0)

40.1.4 ECC Refactoring

Refactoring how elliptic curve groups are stored, sharing representation and allowing better precomputations (eg precomputing base point multiples). [Completed in 2.5.0]

40.1.5 Performance Improvements

The eventual goal would be performance parity with OpenSSL, but initial target is probably more like "no worse than 30% slower for any algorithm".

[Major improvements to ECC and RSA performance were made between 2.4.0 and 2.7.0, measurement and optimization work is ongoing.]

40.1.6 Elliptic Curve Pairings

These are useful in many interesting protocols. Initially BN curves are the main target (particularly BN-256 for compatibility with Go's bn256 module) but likely we'll also want BLS curves.

40.1.7 TLS 1.3

The RFC process seems to be approaching consensus so hopefully there will be a final spec soon. The handshake differences are quite substantial, it's an open question how to implement that without overly complicating the existing TLS v1.0-v1.2 handshake code. There will also be some API extensions required to support 0-RTT data.

Initial work is focused on features which are included in TLS v1.3 but also available for TLS v1.2 (such as PSS signatures and FFDHE) as well as refactorings which will make the eventual implementation of v1.3 simpler. Assuming no source of dedicated funding appears, a full v1.3 implementation will likely not be available until sometime in 2019.

40.1.8 ASN.1 Redesign

The current ASN.1 library (DER_Encoder/BER_Decoder) does make it roughly possible to write C++ code matching the ASN.1 structures. But it is not flexible enough for all cases and makes many unnecessary copies (and thus memory allocations) of the data as it works.

It would be better to have a system that used (a simple subset of) ASN.1 to define the types as well as encoding/decoding logic. Then new types could be easily defined. This could also obviate the current code for handling OIDs, and allow representing the OIDs using the natural OID tree syntax of ASN.1.

Another important feature will be supporting copy-free streaming decoding. That is, given a (ptr,len) range the decoding operation either returns an error (throws exception) or else the decoded object plus the number of bytes after ptr that contain the object, and it does so without making any allocations or copies.

It will probably be easier to be consistently allocation free in machine generated code, so the two goals of the redesign seem to reinforce each other.

40.2 Longer View (Future Major Release)

Eventually (currently estimated for 2020), Botan 3.x will be released. This schedule allows some substantial time with Botan 2.x and 3.x supported simultaneously, to allow for application switch over.

This version will adopt C++17 and use new std types such as string_view, optional, and any, along with adopting memory span and guarded integer types. Likely C++17 constexpr will also be leveraged.

In this future 3.x release, all deprecated features/APIs of 2.x will be removed. Besides that, there should be no breaking API changes in the transition to 3.x
